AN ILLUSTRATED JOURNAL

PUBLISHED WEEKLY

VOLUME XIII

JANUARY—JUNE 1889

NEW YORK
N. D. C. HODGES

1889

INDEX TO VOLUME XIII.

- Academy of Science elections, 321; papers, 320.
 Accumulators, 2 7.
 Acropolis, 41.
 Advertising by doctors, 137.
 Africa, 42; discoveries in Central, 442; resources of, 6 4.
 Agassiz, Augustus, 5.
 Agricultural map of America, 178; stations, utility of, 219.
 Allen's English Restoration and Louis XIV., 127.
 Alloy, a new, 2 9.
 Aluminum manufacture, 260, 499.
 Analysis of air and war, 175.
 Anatomical memoranda, 158.
 Andrews and Stoddard's Grammar of the Latin Language, 12.
 Anemometer constant, 204; factor, 248; the Robinson, 268, 269, 367.
 Anthropological Society, Women's, 60, 240.
 Anti-friction metal, 392.
 Antiquarian Society, 340.
 Antlers, clustered, 321.
 Archeological expedition, Hemenway, 8.
 Archeology of District of Columbia, 38.
 Archery, national school of, 478.
 Arch ramp, 255, 266.
 Arctic exploration, 101.
 Arnold's Reports on Elementary Schools, 1853-82, 324.
 Arsenic in fabrics, 119.
 Art, pre-Columbian, 113; schools of the Metropolitan Museum, 140.
 Asphaltenes, 498.
 Asphyxiation by illuminating-gas, 437.
 Association for the Advancement of Science, 139, 479.
 Autobion monument, 13.
 Austen's Chemical Lecture Notes, 223.
 Australian exploration, 441.
 Baconian method in science, 112.
 Bacteria in the glaciers, 119.
 Baking powders, 296, 423.
 Baldness, 176.
 Balloon, 78.
 Balzac's Louis Lambert, 65; Sarahpita, 507.
 Barnard, President A. T., death of, 338.
 Battle on the Battle of the Swamp and the Capture of Canada, 13.
 Base-line, Los Angeles, 157.
 Batteries, Julien storage, 13; new secondary, 35; secondary, 274, 366, 436; storage, for street-cars, 331.
 Battery, Axa, 101; Clark, 297; Detroit secondary, 297; Macneon, 194.
 Beans in prehistoric Arizona, 233.
 Beer production, 349.
 Bell, a new Mountain of the, 362.
 Bellise, 156.
 Bennett and Murray's Hand-Book of Cryptogamic Botany, 408.
 Benzole acid in beers, 440.
 Bernheim's Suggestive Therapeutics, 265.
 Bessel's Psychic Life of Micro-organisms, 185.
 Binger, Capt., explorations of, 404.
 Birds, Cucullaris propatagialis in oestrine, 16; destruction of, 441; soaring of, 15, 31, 71, 151, 169, 187, 201, 245.
 Births, triple, 110, 132.
 Bismuth, voltaic current from, 398.
 Blavatsky's The Secret Doctrine, 89.
 Boats, nitrous oxide, 155.
 Boats, wild, 237.
 Boaz, submarine, 59, 300.
 Bolders, design of, 321.
 Book-keeping, the decline of, 260.
 Bore in Hangchow Bay, 328.
 Boston Society of Natural History officers, 341.
 Bowditch's Hints for Teachers of Physiology, 368.
 Brake, electric, 411, 439.
 Brick-work, strength of, 181.
 Bridge, submarine, 500.
 Bridgman, Laura, death of, 421.
 British Columbia, mineral wealth of, 436; notes from, 364.
 Broch, O. J., death of, 180.
 Bronze, Tobin, 320.
 Browning's Aspects of Education, 25.
 Brown's Treatise on Spherical Trigonometry, 468.
 Buds, Pests, unhealthiness of, 421.
 Building-stones of East Texas, 295.
 Bulgarian population, 380.
 Butter-making, 328.
 California, colonization of Lower, 255.
 Calorimetric experiments, 379.
 Canal, Corinth, 359, 401; Manchester ship, 181.
 Canal-locks, propulsion, 278.
 Canal-lifts, 481.
 Cancer contagion, 437.
 Carus's Fundamental Problems, 484.
 Cases's Physical Realism, 165.
 Cass's Treatise on Spherical Trigonometry, 468.
 Census machine, electrical, 20; the next, 442.
 Chambers's Encyclopaedia, 285.
 Characters, inheritance of, 236.
 Chemical experiment, 449; re-actions, 240; society, 462; study of apple-twigs, 481.
 Cherokees, the Eastern, 120.
 Chevrolat, Michel Eugene, 271; funeral of, 431.
 Child-labor, 121.
 Chimney corrosion by wood soot, 460; draught, 358; repai-rer, 439.
 Chinch-bug in Arkansas, 441; in Illinois, 275.
 China-treaty, 387.
 Chrome yellow as a poison, 347.
 Church's Mechanics of Engineering, 468.
 Churches, paper, 430.
 Cicada, periods, 358.
 Clark University, 321, 360, 462.
 Classics and Moderns, strife of, 480.
 Claus's Elementary Text-Book of Zoology, 448.
 Clintonite, 370.
 Clouds, vapour, 441.
 Cloud and fog, 487.
 Cloud burst, 459.
 Coal-questions in England, 1-3.
 Coal-bigger, for, C. C. 250.
 Coal mining machines, electrical, 2.
 Coals, Kansas, 217.
 Coasts of the Baltic, secular rising of the, 461.
 Cobra, skin in, 237.
 Coffee adulteration, 400; artificial, 328.
 Colgate University, 501.
 College admision, 358.
 Colorado climate, 174.
 Color-blindness, 32, 41, 170.
 Com-bustion, spontaneous, 277.
 Com-position, curves of, 92.
 Congress, agricultural, 1890, 437; anthropological, 141, 339; botanical, 281; electrical, 312; labor, 400; philosophical, 320; sanitary, 321; zoologicals, 320.
 Congresses at Paris, 361, 381.
 Connecticut Fundamental Orders of, 90.
 Consumption, 482; contagiousness of, 137, 162; germ theory in, 3; prevention of, 462, 465.
 Conyers's Marriage and Divorce in the United States, 304.
 Copper, price of, 253.
 Copyright, international, 102.
 Coral islands, origin of, 236.
 Cory's Hypnotism or Mesmerism, 50; The Birds of the West Indies, 65.
 Cotton fabric, 251.
 Crane's La Société Française au Dix-septième Siècle, 507.
 Crematory, the Hughes, 477.
 Criminals, insane, 340.
 Crops in C. Hornia, 499.
 Cruiser, submerging monitor, 229.
 Cruisers, the two-houson ton, 471.
 Cucumber disease, 380.
 Cures, psychic, 406.
 Dairy commissioner of New Jersey, report of, 366.
 Dan, Robt., death of, 401.
 Dance, Blackfoot sun, 215.
 Dann's German Commercial Correspondence, 148.
 Date-stamp, elect ic, 160.
 Deane, Robert, the leading Book, 149.
 Deaf, study of, 392; teaching language to, 402.
 Deaf-mute instruction in Cincinnati, 482.
 Deaths by lightning, 369; of English scientific men, 324.
 Defective classes, census of, 38.
 Degeneration of the race, 57.
 De Guimps's Pestalozzi, 445.
 De la Rue, Warren, death of, 359.
 Deuver formation, size of the, 250.
 Deodorant, a new, 119.
 Derelict schooner "W. L. White," 117.
 Dines, P. Jessor John, appointment of, 321.
 Dialect Society, 322.
 Dictionary, science and the, 103.
 Diphtheria, 215, 257, 318; transmission of, 119.
 Diseases of menagerie animals, 30.
 Disinfectant, mercuric chloride as a, 62.
 Disinfectants, 61.
 Distilleries in Russia, 380.
 Dollinger, Ignatius, 360.
 Draper memorial, 322.
 Drowning cases, 421.
 Dues and strength, 326; purity of, 218.
 Du Bois-Reymond, Dr. Paul, death of, 360.
 Dupuis's Elementary Synthetic Geometry, 468.
 Dyeing and bleaching laboratory, 141.
 Dynamite gun, 56, 82.
 Dynamo, a new, 326; designing, 235; the Continuum, 17; Westinghouse, 451.
 Earthquake in Japan, 500; in Liguria, 143; in Pennsylvania, 268.
 Eclipse of Jan. 1, 7.
 Economic Association, '68.
 Edison's works, 161.
 Education, encouragement of higher, 219; in Germany, primary, 458; in India, 481; in Russia, 401; of child widows in India, 358.
 Educational Museum for Texas, 101.
 Egypt, races of, 159.
 Elder, the, 181.
 Eiffel, Gustave, 406.
 Eiffel Tower, height of, 350, 499.
 Electric apparatus, the Clark, 494; conductor, a large, 230; conduit system, 372; course at Columbia, 378; currents by mechanical action, 101; distribution, 81; door-opener, 294; drawbridge, 312; engineering at Columbia, 81, 901; Light Association, 4, 154, 460; light on the eyes, 367; lighting by small engines, 2-6; lighting in Europe, 337; oscillations, Hertz on, 79, 98, 137; power in mines, 473; power station, 251; regulator, Wagner, 27; system, Bentley-Knight, 373; system, Sperry, 192; system, Western, 351; tramway in England, 259; underground system, 433; welding, 437.
 Electricity and ether, 109; and light, 158.
 Electroplating glass and porcelain, 500.
 Elephant, skeleton of large, 421.
 Elevator stop, 237.
 Elroy's Annual Report, 102.
 Elizabeth Thompson Science Fund, 461.
 Emin Pasha, 24, 238.
 Empire, our future, 38.
 Energy, conservation of, 400.
 English Westinghouse, 355; working at a fixed cut-off, 440.
 Entomological Club, 479.
 Ericsson Coast Defence Company, 236.
 Ericsson, John, 139, 159, 299.
 Error, genesis of, 164.
 Essex Institute, Salem, 279.
 Ether and the earth's atmosphere, 390.
 Ethnological comparisons, 159.
 Ethnology, report of Bureau of, 64.
 Examination and education, 323.
 Examinations, English, 309.
 Excavations at Paris, 159; by freezing, 274.
 Excelsior classes in Australia, 342.
 Exhibition, geographical, 240; graphic, at Stuttgart, 281; in Birmingham, 281; international novelties, 406; Paris, 1889; Paris, United States of the, 142; travelling platforms in the Paris, 401.
 Exhibitions, floating, 380.
 Feldspar, or feldspar, 16.
 Fertilizer analyses, 439.
 Filters, 437.
 Fire alarm, 191; brigade in Paris, 197.
 Fish in isolated waters, 16, 225; Commission experiments, 60.
 Flowers, double, or factually produced, 441.
 Fly as a disease-carrier, 506.
 Flying-ship, 237.
 Fly-wheels, 467.
 Fog, 116, 429; dissipation of, by electricity, 59.
 Food analysis, 214; decomposing, 483; inspection, 196; requirements of man, 360.
 Footnotes, 380.
 Force, lines of, 234.
 Forests, Adirondack, 218.
 Fossil wood, 11.
 Franklin Institute awards, 298.
 French Association for the Advancement of Science, 140.
 Fruits, 360.
 Fruit-trees in southern California, 321.
 Fungi, study of, 360.
 Galton's Natural Inheritance, 366.
 Gallie and Kutter's General Formula for the Uniform Flow of Water in Rivers and Other Channels, 302.
 Garbage-disposal, Fledschmann system of, 115.
 Gas, natural, 119 in Ohio, 215.
 Gaslight, improved, 96.
 Gas-spring, a deadly, 130.
 Geese, long memory of, 400.
 Geographic Society, 11; teaching, 317.
 Geological Society of America, 8, 400; Survey, 20; Survey report, 342; Survey of Nebraska, 61; Survey of New Jersey, 452.
 Geography, small, for teach, 305, 226, 269.
 Ge. sets, soaping, 282.
 Gibson's Text-Book of Elementary Biology, 222.
 Gilman's Profit Sharing between Employer and Employee, 328.
 Glaciation in Greenland, 121; of Canada, 399.
 Glass, conductivity of, 60.
 Glycerine for sharpening edge tools, 461.
 Gold producer, 187.
 Gosse's History of Eighteenth Century Literature, 259.
 Gould's ornithological works, 387.
 Gratings, theory of, 419; use of, 418.
 Greek Statics for Beginners, 481.
 Greek temple painting, 181.
 Greenhouses, warming, 359.
 Greenland expedition, 501; Dr. Nansen's journey across, 439, 477.
 Greenlanders, East, 384.
 Gum-arabic, artificial, 361.
 Gun, pneumatic, 151.
 Gunpowder, a new, 298.
 Guns, modern, st of, 328; quick-firing, 298.
 Hamilton's Text-Book of Pathology, 445.
 Harper's First, Second, Third, and Fourth Readers, 285.
 Harvard College, vote of officers of, 101.
 Health a public duty, 298; association, 505; Bureau of, 10; National Board of, 215; report of the New Hampshire State Board of, 60; report of New York, 478; report of New Jersey, 345; report of New York, 304; report of Providence, 466.
 Heat, sources of, 329, 349.
 Heating and ventilating, 334.
 Hemenway expedition to the Everes, 29.
 Henshall's More about the Black Bass, 13.
 Historical Association, 7.
 Holbrook's Eating for Strength, 12.
 Home Gymnastics for the Well and the Sick, 435.
 Home study, 480.
 Horns of the prong-buck, 70.
 Horse-flesh as food, 422.
 Humphrey's Favorite Authors for Children, 11.
 Hurricanes, West India, 254, 339, 424.
 Hypnotism, German works on, 125.
 Ice water, 506.
 Incandescent lamps, efficiency of, 435.
 Indian relics from Florida, 61; from North Carolina, 92.
 Indiana Academy of Science, 7, 338.
 Induction coil, 252.
 Industrial tabeaus, 301.
 Inebriate-asylums, 159.
 Inebriety, Association for Study of, 7.
 Insecticides, 357, 393.
 Insomnia, 367.
 Iron industry in the Southern States, 11; silicated, 238; smelting in China, 300.
 Irrigation in California, 110; survey for, 61.
 Ivory varnish, 332.
 Jacob's Physiological Notes on Primary Education and the Study of Languages, 367.
 Jade in Alaska, 88; question, 121.

Janau's French Commercial Correspondence, 148.
Johns Hopkins Hospital, 149, 217.
Johns Hopkins University anniversary, 139; needs, 162.
Kangaroo extinction, 480.
Kansas Historical Society, 140.
Katydid, color of, 32, 71.
Ketchum's Botany for Academies and Colleges, 239.
Kidder, J. H., death of, 321.
Kilmas Ndjaro, 324.
Kilogram, alloy of the standard, 399.
Kirk's When Age Grows Young, 133.
Klein's Bacteria in Asiatic Cholera, 446.
Klein's Elements of Machine Design, 89; Gear Tables for lay-out of accurate Tooth Profiles, 89.
Kongo, commerce on the, 20; European vegetables of the, 261; French, 11.
Koreans, habits of, 230.
Labor in Russia, 474.
Laboratory, Marine Biological, 301, 303.
Lake basins of the St. Lawrence, 32.
Lakes of St. Joaquin valley, 503.
Language, an international, 241.
Languages, bibliography of the Iroquoian, 157.
Laurie's Occasional Addresses on Educational Subjects, 201.
Lead-polluting, 319.
Leffmann and Beam's Examination of Water for Sanitary and Technical Purposes, 446.
Legal regulation of medical practice, 136.
Leland Stanford in 1904, diversity, 399.
Letters, frequency of, 448.
Levmore and Dewey's Political History since 1815, 166.
Light jar discharge, 258.
Leyden Museum, 320.
Libraries, circulating, 175; public, medical, 137.
Lietze's Modern Heliographic Processes, 13.
Life of man and woman, 280.
Light and electricity, 327; and magnetism, 273; electric, Edison patents for, 23, 130; electric, in land warfare, 23; electric, in the Patent Office, 25; Loomis electric system, 229; velocity of, 193; without heat, 34.
Lighting, Ball electric, 18; Westinghouse electric, 1. Lightning-conductors, earthing of, 319.
Lignite industry in Ohio, 274.
Lime, origin of phosphate of, 144.
Lime-burners and consumption, 258.
Lock's Elementary Statics, 470.
Locomotive, a double, 430; electric, 233; Strong, 438.
Locomotives, compound, 320; soda, 420.
Loco weed, 176.
London from a sanitary point, 153.
Lougman's New Atlas, 283.
Lucas's Geography of the British Colonies, 166.
MacDowall's Curve Pictures of London for the Social Reformer, 327.
Magnetic action of currents, 235; storms, 347.
Magnetism and sunspots, 141.
Malaria, 119; microbe, 173.
Man of Nip, 232.
Manganese, preparation of, 504.
Manual training in the conditions of, 22.
Marriage ceremonies of the Bilqua, 505.
Marsh vegetation, 5 0.
Martin and Wetzler's Electric Motor and its Applications, 446.
Massachusetts Agricultural College, 341; Institute of Technology building, 400.
Mad and the Roman Catholic Church and the School Question, 23.
Measles in Scotland, 262.
Merriman's Treatise on Hydraulics, 201.
Meteorological exhibition, 230.
Metric system, 273, 292.
Mexico, exploration in, 265.
Mica and tin ores, 481; as a lubricant, 439; conductivity of, 298.
Michelson, Albert A., presentation of Rumford medals to, 281.
Micro-organisms in inflammation, prize for essay on, 469.
Milk, poisonous, 86; supply, 175.
Mill, an acoustic, 214.
Mineral products of the United States, 455.
Mineralogical Club, New York, 182.
Minerals and synonymies, 438.
Mines and metallurgy congress, 351; electric motors for, 60, 195.
Mining industries in Siam, 184.
Models, deep sea, 191.
Molar, supermagnetic, in man, 16.
Montgomery's Leading Facts of French History, 388.
Morphine habit, 277.
Motor, alternating current, 305; C. & C. electric, 153, 341; the Denison, 211; the Tesla, 323.
Motors for balloon experiments, 133.
Mound in Calhoun County, Ill., 349.
Mound-builders, 123.
Mounds, empty, 187; of Ohio, 110.
Mushrooms, edible, 453.
Music, teaching girls, 482.
Myths of China, 123.
Nails from scrap-iron, 298.
Naptha as fuel, 500.
Naturalists, Society of, 23.
Navajo industries, 89.
Navy, electric plants in the, 100.
Newell's Outlines of Lessons in Botany, 403.
Niagara Canal 122.
Nichol's Francis Bacon, his Life and Philosophy, 327.
Nickel, magnetic properties of, 23.
Nineteenth Century Club, New York, 459.
Nitrogen in soils, 361, 400.
Norway, ancient population of, 311.
Nurses, mortality among, 276.
Obesity, treatment of, 297.
Objectives of short working distance, 140.
O'Brien's Laboratory Guide in Chemical Analysis, 463.

Observatory, a popular, 109; at Arlington, 61; at the Vatican, 483; at Hill, 321.
Ocean currents, 438.
Oham, statue to, 181.
Oil on water, 10.
Oil-bearing territory, 299.
Oils, solid matter in, 338.
Olliphant's Scientific Religion, 148.
Omaha, habits of, 60 153.
Optium-poisoning, 430.
O'Reilly's Greenland, 150.
Ores of Nickel Mountain, 10.
Oriental Society, 139.
Osteological notes, 488.
Overcoats, 175.
Ozokerite, 280.
Paris, sanitary condition of, 422.
Pasteur Institute, 87.
Pasteur's method, 3.
Patents in Japan, 361.
Paul's Principles of the History of Language, 506.
Paving, India-rubber, 101; steel, 237.
Paving-brick, 335.
Peabody Museum, 4 7.
Peas, quality of, 340.
Penicillin, corporal, 216.
Pepper plant, 410.
Perfume flower farming, 481.
Permian rocks of Texas, 92.
Petroleum as a fuel, 249; as an illuminant, 180; in Pennsylvania; vapor and air, 280.
Phantom portraits, 400.
Philosophical Society, 11.
Photograph developing, 437.
Photograph production, 401; washing-dishes, 501.
Photographs of true chromatic value, 401.
Photography and its possibilities, 371.
Physic, 280.
Physiological Association, 6.
Pile-driving by water jet, 437, 500.
Platinum, 232; in British Columbia, 290; in place, 290.
Plumbing, sanitary, 137.
Poison, whiskey as antidote for rattlesnake, 338.
Polar explorations, 240.
Postage stamp, danger in the, 137.
Potato, dried, 277.
Pottery days of Texas, 293; industry in the United States, 136.
Powder, Heughe's, 359.
Precious stones, American, 236.
Preyer's Development of the Intellect, 166.
Princeton College girls, 293.
Proctor's Student Atlas, 305.
Prunes in France, 210.
Psychos and science, 33.
Quarantine conference, 296.
Quartz as an insulator, 366; in eruptive rocks, 232.
Rabbit pest in Australia, 258.
Race between pigeons and bees, 3 8.
Railway accidents, 300; Alleghe electric, 35; Asheville electric, 80; Atlantic City electric, 80, 493; blizzard on electric 50; Boston electric, 80, 493; collisions, 281; Daft electric, in Cincinnati, 391; Daft motor on, 23; electric, for Chattanooga, 3; electricity on New York elevated, 133; Jullien electric, 30; rail, White's, 296; Reckenza electric, 80; St. Joseph electric, 232; snow-storms on electric, 80; Sprague electric, at Reading, 116; Topeka electric, 319; White electric, 33.
Railways, cable, 413; electric, 173, 212; electric, in China, wires for, 397; in Central Asia, 161; in China, 375.
Rainfall and latent heat, 369; of the Pacific slope, 457.
Ran for war-ships, 496.
Rame, 75, 489.
Rat catching, 338.
Rattlesnake's rattle, 3 5.
Rau's Psychology as a Natural Science, 314.
Research in Bombay, 401, 489.
Resistance of mercury, 195.
Rheumatism, 258.
River pirate, 108; pollution in Connecticut, 502.
Roof-g, 309.
Rose, a large, 420.
Rose Polytechnic Institute, 117.
Royal Society, Canada, 296.
Runk's Elements of Plane Analytic Geometry, 149.
Russell's process s. Bower-Barff, 363.
Salomon's The Slidj in the Service of the School, 25-Samoa, 85.
Sanborn's Go to the Ant and Learn Many Wonderful Things, 488.
Sanitarium among cow-stables, 309.
Sanitary ceilings, 497; precautions in Florida, 10.
Sanderson's Insects Injurious to Fruits, 239.
Sawdust explosion, 182.
Scarlet-fever, 318.
School, technical, in Paterson, 259.
Schoolroom as a factor in disease, 21; space, 277.
Schools, military and naval, in China, 435; of New Jersey, 82; New York, 42, 102, 122; New York, political influence in, 62; science in, 182.
Science at Cambridge, Eng., 331; teaching in England, 278.
Sechometer, Ayrton and Perry's, 319, 369; new form of, 213.
Seed-trade in California, 440.
Sense-associations, 105.
Sewage purification, 279.
Shad, Atlantic, 237.
Sheet metal from the molten state, 430.
Ship, a fire-masted, 236; Halfway, Tehuantepec, 839.
Ships, corrosion of steel, 338.
Shortsightedness in the young, 481.
Sight, fatigue of, 41.
Signalling among primitive peoples, 121.

Encyclopaedia Britannica.

POPULAR REPRINT. SOLD BY SUBSCRIPTION ONLY.

We are publishing a popular reprint of the Encyclopaedia Britannica at \$2.50 per volume, bound in cloth of the best quality. This is less than one-third the price of the original English edition, in the same binding, published by A. & C. Black, of Edinburgh, which edition we are reproducing, page for page, plate for plate, map for map, and volume for volume.

The same word begins and ends on any given page, as it does on any given page of the original edition. The same number of volumes (24) completes our set, as will the original, and at about half the price of the other 2 subscription editions, both of which are printed from the same original English edition, from which we also reprint.

No such book has ever been put upon the market, of such size and quality of binding (the latter as good as that of any other edition of the Britannica), for so low a price. It is a well-known fact that it contains the highest character of knowledge and literature in the world: written by the most eminent living authors, the articles signed by 7,500 eminent specialists will form in the aggregate over five-sixths of the contents of the work. In fact, it is the greatest work of its kind that has ever been published in the English language.

We are reproducing the latest volumes issued of the (ninth) original ENGLISH edition which has just issued its 24th and completing volume.

In offering the Encyclopaedia at this unprecedented low price, the publishers have reason to believe the opportunity will not be lost by the purchasing public.

The Encyclopaedia Britannica is a library in itself and the knowledge of centuries focused: the essence of all books crystallized.

One of our chief desires is to obtain as subscribers all those who have ever entertained an idea of owning the Encyclopaedia Britannica, but hesitated on account of the high price.

Truly the "Best is Now the Cheapest."

THE SECRET DOCTRINE.

The Synthesis of Science, Religion and Philosophy.

BY H. P. BLAVATSKY,

Author of "ISIS UNVEILED," and founder of the Theosophical Society.

2 Vols. Royal Octavo. Cloth \$10.00.

AN UNPRECEDENTED LITERARY EVENT.

This book is written with the especial aim: "to show that Nature is not a 'fortuitous concourse of atoms,' and to assign to man his rightful place in the scheme of the Universe. . . . to show that the occult side of nature has never been approached by the science of civilization." It is based upon stanzas from the **BOOK OF DZYAN**, an archaic MSS. unknown to the Western world, with erudite commentaries, explanations and elaborations. In the Addenda Modern Science is contrasted with Esoteric Science.

The Darwinian theory of Evolution is shown to be wrong, and it is asserted by the author that the Apes are not our ancestors but are degenerate descendants of prehistoric man.

*The book also attempts to show that all the forms upon the earth have been produced by man who has passed through each one in his evolution.

The Moon is held to be the progenitor of the Earth and not a mass that was thrown off by the latter in cooling.

The author shows enormous erudition, and if readers call the book an invention they must place the writer at the head of the geniuses of the age.

CHARLES T. DILLINGHAM, 718-720 Broadway, New York.

GUARANTY INVESTMENT COMPANY

CAPITAL \$250,000.

Hon. ALBERT H. HORTON (Chief Justice, Kansas Supreme Court), Topeka, Kan., Pres't.

7% Guaranteed Farm Mortgages 7%

The Company calls the special attention of Investors to the following points :

- I. All loans guaranteed and interest payable semi-annually at the Importers' & Traders' National Bank, New York.
- II. Unusual fulness of information, not only about the security itself, but about the general development of the section where the farm is located.
- III. An examination each year of the general business of the Company and the Mortgages themselves by a COMMITTEE OF INVESTORS sent for the purpose.
- IV. Many hundred Mortgages taken and NOT A SINGLE FORECLOSURE.
- V. Exhibitions in New York at frequent intervals, of Kansas and Nebraska Farm Products. The Exhibition at the American Institute in the fall of 1888, received the *HIGHEST AWARD* of superiority.
- VI. Monthly Bulletins giving full information about all Mortgages offered for sale.

Address for Monthly Bulletin and Investors' Committee Report for 1888,

HENRY A. RILEY, General Eastern Manager, 191 Broadway, N.Y.

THE NUN OF KENMARE.

An Autobiography, by MARY FRANCIS CLARE CUSACK, late Mother General of the Sisters of Peace. 12mo. 580 pages. With fine portrait. \$1.50.

"Revelation of the Roman Church from the Inside—The Autobiography of Mary Francis Cusack—Conventual Life Unmasked—The Catholic Hierarchy with the Light Thrown on it—A Woman Tells What She Knows."—Boston Herald.

"The Nun of Kenmare,—a book which will prove a bombshell.—Her reasons for giving up her life-long work.—Jealousy of priests and prelates.—Early Life.—Literary labors."—*British American Citizen*.

"The pathetic story will be read with close attention by those for whom the author has labored so long and so devotedly, and by those of all creeds, sects, and nations who yet believe in Christian charity, and would not see any good work crushed and hampered by jealousy and opposition."—*Cambridge Tribune*.

"The greatest interest has been manifested in this work. The Ticknor house has been besieged by people eager to secure the earliest possible copy, or even any clue to the nature of the contents."—*Chicago Inter-Ocean*.

Sold everywhere. Sent, postpaid, on receipt of price, by the publishers.

TICKNOR & CO., Boston.

Paillard's MUSIC BOXES ARE THE BEST.

They play the best selections from all the

What Scott's Emulsion Has Done!

Over 25 Pounds Gain in Ten Weeks.
Experience of a Prominent Citizen.

THE CALIFORNIA SOCIETY FOR THE
SUPPRESSION OF VICE,
SAN FRANCISCO, July 7th, 1886.

I took a severe cold upon my chest and lungs and did not give it proper attention; it developed into bronchitis, and in the fall of the same year I was threatened with consumption. Physicians ordered me to a more congenial climate, and I came to San Francisco. Soon after my arrival I commenced taking Scott's Emulsion of Cod Liver Oil with Hypophosphites regularly three times a day. In ten weeks my avoirdupois went from 155 to 180 pounds and over; the cough meantime ceased. C. R. BENNETT.

SOLD BY ALL DRUGGISTS.

SCIENCE

FRIDAY, JANUARY 11, 1889.

THE CONTINENTAL DYNAMO.

MANY of the most important improvements that have been made in the last few years in dynamo-construction have been in the direction of greater simplicity and solidity of design, me-

chanically and electrically, and in the better proportioning of the different parts. No radical changes or discoveries have been made; but, if we compare the dynamo of to-day with that of four or five years ago, we will find a greater efficiency, a much greater

THE CONTINENTAL DYNAMO.

chanically and electrically, and in the better proportioning of the different parts. No radical changes or discoveries have been made; but, if we compare the dynamo of to-day with that of four or five years ago, we will find a greater efficiency, a much greater

if it becomes necessary, they may be removed by simply taking off one bearing. There being very little leakage of lines of force, — only a few per cent compared with twenty to forty per cent for an ordinary dynamo, — there is no ill effect on watches brought in its

INTERIOR OF CONTINENTAL DYNAMO.

output of current for the same weight of metal in the machine, and less expense for repair. But while no radical changes in principle have been made, yet some new types of dynamo have been introduced that present important peculiarities. The Continental dynamo, which we illustrate in this issue, seems to be as simple and compact as it is possible to make a dynamo. The pole-pieces and

neighborhood. The advantages of the dynamo seem to be in simplicity and solidity of construction, accessibility of different parts, no leakage of lines of force, and efficiency, while little care is necessary in attendance; and, as it is not high-priced, it is a machine that in general is likely to meet the demands of a wide circle of users.

BALL ELECTRIC-LIGHTING SYSTEM.

ONE of the most peculiar of the many dynamos that have been used or proposed for arc-lighting is that of the Ball Electric Company. From the accompanying illustration it will be seen that two armatures are mounted on the shaft, with one pole-piece for each.

THE BALL DYNAMO.

The armatures are of the well-known Gramme ring type, and are constructed with a large number of separate coils, thus reducing the sparking at the commutators to a minimum. By some it is claimed that the dynamo must be at a disadvantage from the considerable magnetic resistance that the lines of force experience in passing from pole-piece to pole-piece. By others it is said that this is not so, as the lines of force do not close their circuit from pole to pole, but from poles through armatures to magnet-bars opposite; and that from the thinness of the copper windings, and from there being two armature-cores in multiple across a common field, the magnetic resistance is actually less than in other makes

The mechanical construction of the dynamo is excellent, and, from the testimonials contained in the last circular issued by the company, it would seem that the machine can stand the maximum of rough usage with a minimum of repair.

Besides the high-power lamps of 2,000, 1,600, or 1,200 candle-power, the Ball Company advertise smaller arc-lamps of 800 candle-power, for use in stores, etc., and they also provide incandescent lamps to be used on arc-light circuits. They also furnish complete incandescent-light installations.

THE "IDEAL" STEAM-ENGINE.

AN improvement in one of the most important steps in the conversion of heat into power, showing the results of scientific methods applied to the design and construction of the steam-engine, is illustrated on this and the next page. This engine, which is known as the "Ideal," is a more highly developed form of the Ide engine, and is manufactured by A. L. Ide & Son of Springfield, Ill. It was designed to meet the special requirements of electric lighting, such as high speed, small space, perfect regulation, absence of vibration, and economy in the use of steam; and the results shown by actual use prove that the designers of the engine are progressing in the right direction. The engine is compact, perfectly balanced, and self-oiling; and, as it has a rigid double frame with heavy sub-base, it may be run at a high speed without vibration.

The manner of lubricating the guides, cross-head pin, and piston-rod, is shown in the longitudinal section, Fig. 1. The oil is taken up by the crank-pin disks, when in motion, and thrown by centrifugal force upon the guides and piston-rod. The oil wiped from the upper guide by the cross-head slide passes through a tube in the top slide, entering a funnel in the connecting-rod, and thoroughly lubricating the cross-head pin. The peculiar manner of keeping a constant supply of oil in contact with the crank-pin, main bearings, and eccentric, is shown at Fig. 2. Some of the oil thrown off by the revolving disks is caught in the pockets in the disk-hood (Fig. 1). The oil from the upper pocket is conducted by a tube provided with a regulating-cock to a receptacle on the eccentric-strap, whence it passes, after lubricating the eccentric, to a drip-pan underneath, and thence back to the oil-well for further

FIG. 1.

of dynamos. The large output of the dynamo in comparison to its weight, and the small amount of copper used upon its field, seem to testify to the correctness of the latter.

Its advantages, which are of a practical kind, lie in the fact that by distributing the rotating wire on two armatures the number of layers can be reduced, the difference of potential between adjacent turns is less, and therefore there is less liability to burn out, while the excellent ventilation prevents overheating; also, if any thing happens to one armature, the other can be used to run part of the lamps.

use. The oil from the other pocket flows through pipes into pockets cast upon the main bearings. From these points it flows into the grooves and channels connecting with the crank-pin, which is hollow. The centrifugal force carries it into the crank-pin, from which it escapes through holes into the bearing. Thus it will be seen that the main bearings receive constant lubrication, while the crank-pin receives a supply of oil from either side. This method of lubrication is constant, and provides for the most important bearings about the engine. Sufficient oil is placed in the basin under the crank-disks to cause it to flow in streams through both

pipes and in drops to the eccentric, but valves are provided on the pipes so that the supply can be regulated as desired; and the reservoir can be supplied with fresh oil while the engine is running. Besides the saving in oil, these devices keep a clean and presentable engine and engine-room.

The automatic cut-off governor is shown in Fig. 3. It is an isochronous governor, very simple in construction, and responds instantaneously to the slightest variation in load, cutting off the steam at a point that will just do the work and maintain the fixed speed of the engine. It is secured to the side of the fly-wheel, and connects direct through the eccentric on the main shaft with the valve, without the use of gearing, pulleys, shafts, or belts. All its parts are in sight, and are readily accessible for cleaning. It gives an open port at the beginning of each stroke, admitting steam to the piston at full boiler pressure, and varies the point of cut-off as the load requires, from the beginning to three-fourths of each stroke. The speed of the engine remains practically constant, regardless of the change of load or variation of steam-pressure in the boiler, the variation from no load to the full power of the engine being, it is claimed, less than one per cent. The

FIG. 2.

FIG. 3.

dash-pot attached to the eccentric prevents any sudden movement of the weight when a great change of load occurs suddenly. The running speed of the engine may be changed to suit requirements by shifting the position of the lever.

The steam-chest is bored out and fitted with a pair of cylinders or bushings which have supporting bars across the ports, to prevent any possibility of the valve catching upon the ports. The valve is of the hollow piston type,—a hollow tube, with a piston at each end. It is surrounded by steam, which presses equally upon each end, thus perfectly balancing the valve and relieving its pressure, insuring it long service with little wear. The piston-head is a single casting, hollow, and as light as is consistent with strength. The cross-head is a crucible steel casting, with phosphor-bronze slides; and the attachment to the connecting-rod is central, thus avoiding any strain on the piston-rod by angular thrust. The guides are bored out the same size as the cylinder, thus insuring large wearing surfaces and constant accuracy of line with cylinder. This, together with the self-oiling devices, insures cool running, and long service without adjustment. It may be added, that the construction seems to be such as to give the required strength and rigidity for high speeds; ample wearing surfaces are provided; all the parts are made of steel, phosphor-bronze, and charcoal iron, and are interchangeable; and every engine is tested by actual service at the factory.

SCIENTIFIC NEWS IN WASHINGTON.

Does Exposure to the Sun cause the Human Skull to be Harder and Thicker? — Diseases of Menagerie Animals.— The Geological Survey.

Does Exposure to the Sun cause the Human Skull to be Harder and Thicker?

ONE of the most interesting things mentioned by Professor Virchow in his little book just published, entitled "Medical Remembrances of an Egyptian Journey," in which he describes an excursion up the Nile as far as the first cataract, is that the broken skulls on the first great sepulchral fields, dating from Roman times, are as thick and hard as Herodotus says those of the slain Egyptians were in comparison with the brittle ones of the Persians. The Greek historian explains this by attributing it to the early exposure of children to the heat of the sun; and in many parts of upper Egypt the German travellers actually found young children thus exposed during their parents' absence in the fields, in immense clay bowls, resembling in shape a champagne-glass with a stem, into which they were put without shelter.

This discovery by Professor Virchow is interesting, because it at once suggests the question whether the proverbial thickness of the skull of the negro has not been caused by exposure to the sun, and whether it is a peculiarity of savages of tropical countries that their skulls are thicker and harder than those of the inhabitants of temperate and colder countries.

Students of craniology have never made any investigation to ascertain whether the skulls of different races vary in degrees of hardness. It would be almost impossible to make such an inquiry. As is well known, the human skull increases in hardness from childhood to maturity and age. A miscellaneous collection of skulls of any given people would therefore be of no value in such an investigation. To obtain a collection of skulls of a number of nationalities, that should be taken from subjects all of the same age, to have them all similarly prepared and in sufficient numbers to make it possible to draw any general conclusions from their comparison with each other, would be manifestly impossible.

More attention has been given to the relative thickness of different skulls, or rather to their weight, from which their thickness may be inferred. Of the large collection of crania in the Army Medical Museum at Washington, the thickest are those of negroes and Alaskan Indians. The skulls of other Indians, both of North and South America, in tropical or temperate climes, and of the Eskimo, do not appear to be particularly thick. Among the ancient

Peruvian skulls recently received by the museum, and the ancient crania collected in Arizona last summer, there are frequent individual variations in thickness, but no tendency to unusual thickness. The conclusion from these facts is, that exposure to the sun probably does not cause thickness of the human skull.

In connection with this subject, it is interesting to note, that, among the Australians the *sinus frontalis* is generally found to be solid in the males, instead of being hollow as in the skulls of other races. This bone in the male Australians generally extends straight across the head, the lower side overhanging the eyes so that they seem to look out from under it, while in the North American Indians a modification of shape deprives them of that heavy look about the forehead. The heavy *sinus frontalis* of the Australians, of course, increases the weight of the skull.

Diseases of Menagerie Animals.

At the meeting of the Biological Society, Mr. F. A. Lucas read a paper on "The Diseases of Menagerie Animals." He showed that menagerie animals are extremely liable to disease; and this is almost as true of those born in captivity as of those which are captured when full grown.

Young animals suffer greatly from caries, owing to lack of proper diet, and their bones are very generally soft, swollen, and misshapen. The maxillaries are especially liable to be attacked during the period of teething, and the facial region is in consequence very much distorted.

Diseases of the lungs are very prevalent among menagerie animals, tuberculosis being exceedingly common among monkeys, and found among other animals less frequently. Pneumonia is a frequent cause of death, and birds as well as mammals are liable to be attacked by this disease.

The following is a list of animals examined, where the cause of death was fairly established:—

- Macaque (*Macacus cynomolgus*).—Tuberculosis.
- Gray fox (*Urocyon virginianus*).—Pneumonia. This specimen also exhibited a very bad case of intestinal catarrh and inflammation of the bladder.
- Badger (*Taxidea americana*).—Pneumonia.
- Elephant (*Elephas africanus*).—Pneumonia.
- Lynx (*Lynx rufus*).—Uræmic poisoning (in two cases).
- Black bear (*Ursus americanus*).—Killed. Had been sick for some time with catarrh of stomach and intestine.
- Minot bird (*Eulabes affinis*).—Congestion of lungs.
- Parrot (*Amazona ochroptera*).—Congestion of brain (?) This bird died suddenly, and all organs were healthy. The blood-vessels of the brain were much congested.
- Parrot (*Amazona Levaillantii*).—Tuberculosis.
- Tooth-billed pigeon (*Didunculus strigorostris*).—Disease of liver, that organ being converted into a hard, waxy mass adherent to sternum.
- Pigeon (*Columba livia domestica*).—Disease of liver, same as above.
- Eagle (*Haliaeetus leucocephalus*).—Fatty degeneration of liver.
- Night heron (*Nyctherodius violacens*).—Congestion of lungs.

The Geological Survey.

Appropriate committees of the Senate and House are considering, with very favorable tendencies, the bill appropriating \$600,000 for the erection of a building for the Geological Survey, on the public reservation near the Smithsonian, where grounds have been allotted to it. The plan submitted by Major Powell contemplates a solid and compact rectangular structure, covering 100 by 300 feet, five stories high, with hipped roof. It will be of Seneca sandstone (like the Smithsonian), or of selected red brick with sandstone buttresses, trimmings, and belt courses, and overground basement of same. The general arrangement will consist of a series of large, well-lighted rooms, averaging 16 by 24 feet, disposed about a spacious central court lighted from the top, and with tessellated floor. In this court the working collections of the survey will be open to inspection. The preliminary ground plans and elevations have been prepared by Messrs. Victor Mindeleff and Delancey W. Gill of the Geological Survey.

THE TASK OF STATE WEATHER SERVICES.

PROFESSOR FRANCIS E. NIPHER, in an interesting pamphlet on the rainfall of Missouri, takes occasion to urge the establishment of State weather services. "The State weather service," he says, "bears the same relation to the national service that the State Government bears to the National Government.

"There are many large storms, of great severity, which damage shipping and endanger life. The Signal Service has done a great work in giving warning of these storms. Shippers and dealers in provisions and fruits find the cold-warm warnings of the greatest value. In all large cities the approach of a 'warm spell' is known through the Signal Service predictions, and thousands of tons of meats are hurried to cold storage warehouses, and the opportunity to ship other provisions which must be kept from freezing is anticipated and made available. It is not saying too much to say that it would be impossible to carry on the shipping business of the country as it is now carried on, without the aid of the national weather service.

"But each State has its own peculiar industries, advantages, and interests. It should provide for a thorough study of its own climate, and should distribute published reports for the benefit of those who may desire such knowledge.

"There is another field which peculiarly belongs to the State weather service. The weather which is of greatest importance to the farmer is the weather of harvest. During that time storms are usually very local. They may cover a few counties only, and inflict immense damage. People living in the city can learn from the Signal Service that there will be 'local rains in Missouri,' but nobody knows where in Missouri they are going to locate; and even this information reaches the farmer only after the rain is over, if at all.

"The local peculiarities of these storms require study in each State. Very much has been done in this direction in Iowa and by the New England Meteorological Society. Such work should be at once begun in our State. In three or four years we should be familiar with the behavior of these storms, and this knowledge could be given to all.

"In 1893 the telephone will become public property, and it will then be possible for county telephone services to be established, putting each farm in communication with a county seat. Telephone service can be rendered for a sum which will be utterly insignificant when compared with the advantages which it will bring. Farmers can then keep informed of the markets, can sell their produce before leaving their homes, and will be able to save much time which they now waste during the busy season of harvest. This is all so apparent that it is needless to discuss it further. In addition, there will grow up a system of harvest storm warnings. It will be very easy for any county telephone system to give its subscribers a general warning of an approaching thunder-storm, and to transmit that information to such other counties as may be in danger. The exact details of this scheme may be left to the director of a State weather service to work out. It seems certain that this can and will be done, and there is no reason that this should be done by the national weather service."

COMMERCIAL GEOGRAPHY.

The Development of Commerce on the Kongo.

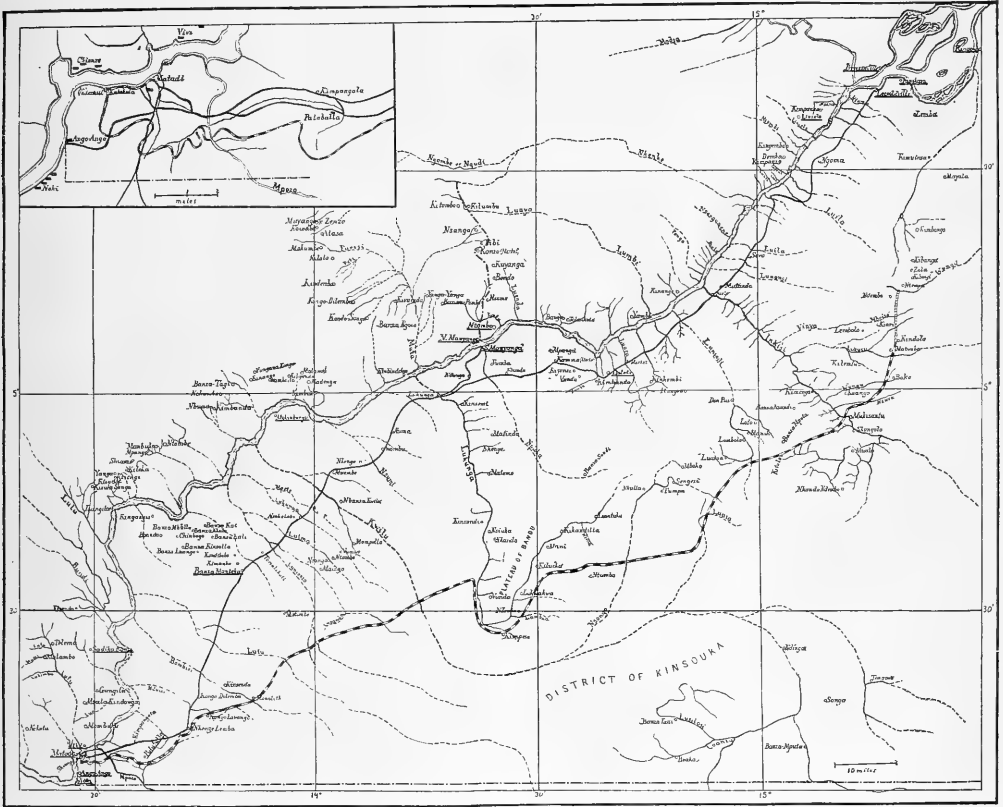

The Belgian Compagnie du Congo pour le Commerce et l'Industrie is pushing on its enterprises vigorously. The most important among these for the development of the resources of Central Africa is the railroad from Matadi to Stanley Pool, connecting the navigable upper Kongo with the highest point that can be reached by steamers. In the past year a corps of engineers was engaged in surveying this line, which offers peculiar difficulties on account of the deep gullies cutting the line to be followed by the road at right angles. At a recent meeting of the shareholders of the company, M. Cambier, chief engineer of the expedition, gave a report of his proceedings, which has been published in a recent number of the *Mouvement Géographique* from which we take the following statements and the accompanying map.

It will be noticed, that while the old caravan route runs approxi-

mately parallel to the Kongo, and crosses its affluents near their mouths, the railroad either crosses these rivers near their sources or keeps on the divides between these river systems. Thus the deep gullies and valleys are avoided, gentle slopes prevailing on the plateau. Considerable difficulty was encountered in climbing this highland which falls abruptly to the river. It was found impossible to ascend it by one of the tributaries of the Kongo coming from the south, as they run in inaccessible gorges. But fortunately a depression was found a short distance below Matadi, from which point the projected road ascends the highland. The road will cross the tributary Mpozo on a bridge, and, after having avoided the plateau of Palababa by a *détour* to the south, it takes an east-

about 300 feet above the Kongo, which are traversed through narrow and tortuous valleys. Later surveys show that a better line may be found farther to the west. Although it will be some time before work on this line is taken up, the results of these surveys show that it may be constructed without incurring extraordinary expense. Preliminarily the establishment of a regular connection with the upper Kongo by means of oxen is contemplated.

The commercial reconnaissance of the upper Kongo region, and the tentative establishment of stations by the Belgian Company as well as by the Sandford Exploring Expedition, have encouraged the promoters of these enterprises to take more energetic action. The two companies have recently joined, and formed the Compagnie

PROJECTED RAILROAD FROM MATADI TO STANLEY POOL, KONGO FREE STATE.

north-easterly direction, until the river Lukunga is met. It seemed at first that some difficulties would be encountered here; but the reconnaissances of the engineers showed that the valley of the river takes a north-easterly turn, and thus they were enabled to follow its left bank without crossing it. No serious obstacles are encountered between the bend of the Lukunga and the Inkissi, the country consisting of hills intersected by small ravines. Between the line and the Kongo rises the plateau of Ngombi to an altitude of 1,600 feet. This part of the country is intersected by deep valleys. The Inkissi, at the point where the railroad is proposed to cross it, is about 350 feet in width. A number of rocks are found in its bed, which will facilitate the construction of a bridge.

East of the Inkissi the population becomes less numerous, and the country is more elevated and sandy. The heights of the hills are clad in forests, and deep ravines intersect the slopes of the plateaus. Approaching Stanley Pool, the line has to pass over hills

Belge du Commerce au Congo, with a capital of 1,200,000 francs, which has for its purpose the establishment of regular commerce with the Kongo basin.

HEALTH MATTERS.

The Schoolroom as a Factor in Disease.

A VERY valuable paper on "The Schoolroom as a Factor in the Production of Disease" was read by Dr. J. A. Larrabee of Louisville, Ky., at the last meeting of the American Medical Association, and is reported in full in the *Journal*. Estimating that one-third the lifetime of every educated person is passed in the schoolroom, it follows that the location, construction, and surroundings of the same are matters of importance. While there has been great advance in these respects, much still remains to be done. In Switzerland the summits of small hills are selected as school-sites.

Schoolhouses should be built in parks, and every thing possible done to make them attractive both outside and within. Ventilation is a matter of prime importance. Among the diseases caused or favored by schools, he places the following: contagious diseases, headaches, eye affections, chorea, and consumption.

This paper was discussed by several of the members of the association. Dr. Lindsley of Tennessee said that there were two points which he wished to emphasize: 1. Medical men must arouse public attention to the necessity for paid medical inspectors. 2. No text-books of hygiene should be put in the schools, because the masses do not get this education. The majority of children leave the schools before reaching the higher classes where this subject is taught. Hygiene should be impressed upon them by every feature of their environment.

Dr. Hibberd of Indiana agreed with Dr. Lindsley in the utter impossibility of teaching children in primary schools enough physiology to be of utility. There are many who are grandfathers who do not know what it is absolutely necessary to teach. Teach youth to observe, and what things they should observe. The trustees of schools understand the necessity for air, light, etc., but they cannot get the money to provide them. Every schoolhouse in the land should be situated so as to face the best direction of the compass, having air and light in abundance; but it will cost a great deal of money.

We must recognize that all children are not exactly alike in their capacity for receiving education; and the present methods are faulty in teaching all children on the same plan. Due regard must be paid to mental and physical variations, and sound minds and bodies cannot be had until this is recognized.

Dr. Hamilton, United States Marine Hospital Service, said that the reason that the majority of German children were myopic was due to the employment of the old black letter. German medical text-books are printed in Roman letters, but for political reasons the black letters are generally used. He believed in the necessity for school-inspectors; and the first thing they should do would be to examine the text-books, the paper of which is often inferior, and the printing but little better. Another feature demanding improvement is the sitting arrangement of a schoolroom. All know the country schoolroom, with its four rows of desks, and windows on either side of the room, which imperfectly light the middle rows of desks.

Dr. Vaughan of Michigan did not believe that all defects in eyesight in school-children are attributable to the schoolroom. If one enters any family room at night, the father and mother will be found sitting on either side of a table on which the light is, and the children are allowed to sit anywhere. More harm is done young girls by sitting up late at night at parties and dances than by all the alleged confinement in the schoolroom. Dr. Larrabee did not refer to the stairs, which are usually selected as one of the fertile sources of disease in young girls; but if one watches a woman go upstairs, she does it with her body bent forward, and swinging from side to side, instead of going upstairs erect. The German method of the climbing cure might be employed advantageously in some of these cases. In Michigan most children are better situated at the schoolhouse than at home; farmhouses, as a rule, from a sanitary point of view, being far from good. The ignorance of teachers on hygienic matters seems to me to be the primary evil.

Dr. Hibberd believed, with Dr. Vaughan, that the fundamental education should be with the teacher. But the architect must also be remembered. This gentleman usually puts his efforts on the adornment of the exterior of the building, and the interior is suited to this. One cannot get architects to give sufficient attention to the interior of these buildings, because it is their aim to produce handsome work.

Dr. Vaughan stated that the plans for school-buildings in Michigan must be approved by the State Board of Health.

ELECTRIC LIGHT AND EYES.—In the *Medical News*, Dr. George M. Gould discusses the question, "Is the electric light injurious to the eyes?" Before proceeding to the direct answer of this question, he refers to the relation of the electric light to general hygiene. Most every one, he says, has a general impression that the electric light is much superior to other methods of artificial illumination, so far as concerns our general health and comfort, but

few could give a reason for the faith that is in them. They will come out of a theatre, music-hall, church, etc., with headaches, lassitude, exhaustion, their bodies bathed in sweat, all resulting in colds and a multitude of major and minor affections, and never utter a word of protest or complaint against the culpable and parsimonious management that permits the vitiation, poisoning, and superheating of the atmosphere by a thousand gas-jets. In the discussion of the question as to the injury to the eyes by the use of the electric light, Dr. Gould refers at length to the literature of the subject, and sums up the whole matter in the following conclusions: 1. As regards general hygiene, the superiority of the electric light over gas as an artificial illuminant is so overwhelming as to admit of no discussion. It is incontestably the light of the future, and the public should not rest until its meeting-places, such as theatres, halls, reading-rooms, churches, etc., are lighted by the most perfect system at its command. 2. A study of the published cases of injury to the eyes by the electric light shows that not one was due to the use of the diffused light as an illuminant. The popular prejudice against such a use of it is absolutely without justification. All the cases reported were of scientific investigators, etc., or workmen about the light, who approached it very closely, gazed at it protractedly, and without protecting colored spectacles. 3. The ocular injury is due, not to the supposed preponderance in the electric-light rays of violet and ultra-violet (chemical or actinic) waves, but simply to the greater number (intensity) of the usual length light-waves. 4. The symptoms of the ocular injury are possibly immediate temporary "retinal paralysis," blepharospasm, central scotomata, chromatopsia, after-images, etc. Within twenty-four hours there come on intense photophobia, lachrymation, ocular pain, a feeling as of foreign bodies beneath the lids, conjunctival hyperemia and congestion, pericorneal circles, etc. 5. The attack usually lasts but two or three days; the prognosis is excellent; the treatment is simply cocaine and atropine instillations and cold or hot compresses. 6. Workmen and experimenters who must approach closely to the electric light should protect their eyes by smoked or tinted glasses, the depth of the tint being greater where the light is more brilliant, the proximity greater, or the exposure longer. In the welding-works the workmen must be particularly careful about this, and must also not expose the skin of the face, neck, and hands to the action of the light. The precaution may not be amiss to advise the curious against testing their eyes by gazing at the ordinary arc and glow lights at short range.

ELECTRICAL NEWS.

The Electric Sugar-Refining Process.

IN the last week the daily press, and the stockholders of the company organized to develop the electrical refining of sugar, have learned that the process does not exist, and that a gigantic fraud has been perpetrated. It is just to remark that many of the electro-technical papers have denounced the scheme from the first. "With the Keely motor, it demonstrates the fact, that, by making large enough promises, a clever adventurer can get a great many people to advance money to promote the most impossible plans. There are few people who will not risk a few hundreds, or even thousands, on the promise of making a million in a short time. The refining process in question was secret from the first. Elaborate precautions were taken to avoid publicity, — a fact that should have at once aroused the suspicion of investors. A large sum of money (\$250,000 to \$350,000) was given the alleged inventor for the purpose of equipping a factory; and a few bags of raw sugar, taken to the works and submitted to the process, apparently came out as refined sugar. In reality this was effected in an extremely simple manner, by substituting previously provided refined sugar for the raw in the secret "electrical" chambers. The whole matter illustrates forcibly what we recently said about electrical investments, that while there are such investments which will give better returns than in almost any other industry, yet, like any thing else that is new and not well understood, it has been and still is the means by which a great deal of money has been obtained from trusting investors, from which there will never be any return.

THE ELECTRIC LIGHT IN LAND WARFARE.—The London *Electrician* describes the following experiments made on Hamp-

stead Heath, for the purpose of testing the capacity of small electric hand-lamps in searching for the wounded men left after a battle, and thus more rapidly than hitherto bringing the sufferers within the reach of surgical aid. The experiments were made by the officers and men of the London Division of the Volunteer Medical Staff Corps, — an organization which already consists of four efficient companies, largely composed of medical students, and for which a fifth company is now in process of formation. The corps, under Surgeon-Commander Norton, accompanied by ambulance-wagons, and provided with stretchers, halted upon one of the Heath roads at a time when the thick mists still hung heavily upon the lower grounds, and having established a field-hospital in a rather dreary-looking spot, poorly sheltered by bare trees, sent out its searching stretcher parties to pick up the bandsmen who had been distributed over the open ground at some distance off, to simulate the wounded left from a fight during the daylight. By the aid of the lamps thus brought into use for the first time, the men sought were found with comparative rapidity, the lights being sufficient also to enable the trained ambulance-men to apply preliminary bandaging upon the spot, and before loading the stretchers, which by other lights at the wagons were guided back to the road. There the men were carefully placed in the vehicles, and conveyed to the field-hospital, where the examining surgeons found very little to correct in the treatment adopted under such disadvantageous circumstances. The results achieved indicate sufficiently well, says the *Daily News*, that the electric light thus used would be of immense value, and tend greatly to reduce the suffering of men left upon the field at the close of a fight.

AN ELECTRIC ROAD FOR CHATTANOOGA. — There has been a very rapid extension of electric street-railroads during the year in all but the Southern States. Here only one very important road has been completed, although several are under contract. The street-car system of Richmond has been equipped with electric motors, and recently the Thomson-Houston Company has opened a short road in Danville. The most important contract in the Southern States since the Richmond road was finished is that recently given by the Chattanooga Street Railway Company to the Sprague Motor Company. The line will be five miles long, and there are on it a number of sharp curves and heavy grades, the maximum being about eight per cent. The road will be newly constructed throughout. Eventually the entire railroad system of Chattanooga will be equipped with electric cars. The present road will have overhead conductors, a small wire fed from a larger wire, — the former over the track, the latter anywhere that is most convenient. The motor-cars will be of the new Sprague type, lately described in this journal.

THE EDISON LAMP PATENTS IN ENGLAND. — There will soon be given a very important decision on Edison's patents for incandescent electric lamps. In this country there has been no direct decision as to the validity of Edison's patents, all of the suits heretofore having been of a preliminary character; but in England and Germany several suits for infringement have been brought by the companies controlling Edison's patents in those countries, and the decisions, with one exception, have been in their favor. It is an appeal from this adverse decision that has just been argued. In the case, Edison's patent was declared invalid mainly because of incomplete specification, Justice Kay holding that a lamp as made by Edison's description was not commercially successful, nor could it be made so. Witnesses on the two sides attempted to make lamps according to the specifications; and those called by the Edison Company succeeded in doing so, while those on the other side uniformly failed. Finally Professor Stokes was appointed as referee, and a number of lamps were made and were tested. Some of these gave out in a few hours, others burned longer. The results obtained would not be in any way satisfactory as compared with our present lamps, nor could a station using these first lamps be run at a cost to make such an enterprise practicable. Professor Stokes reported impartially the result of the experiments, which at the time were generally considered as favoring the Edison patents. Justice Kay decided, however, that the lamps described in the specification never became, nor could ever become, a commercial success. The case on appeal is now before the same court that formerly affirmed

the validity of the patents, and there seem to be strong hopes among those interested that the present decision will be like the former one. The decision of Justice Kay had a beneficial effect on the lamp-trade in England; prices have been reduced, and several firms have put new and improved lamps on the market. At the same time, if Edison is the original inventor of incandescent-lamp filaments, he should be entitled to the benefits of his invention. While the sustaining of a fundamental patent in any industry has a tendency to create a monopoly for a number of years, and restrict competition and decrease the rapidity of progress, yet the ill effect of a failure to sustain a just patent would have the still worse effect of discouraging invention. In the case of Justice Kay's decision on the Edison patents, the fact that the lamps made would not pay to manufacture commercially should have no weight, provided they first embodied the principle on which the present lamps are made; the only changes being in the improved methods and materials taught by experience, these improvements being merely in matters of detail.

THE DAFT MOTOR ON THE ELEVATED ROADS. — The Daft Electric Company continue their experiments with the large motor and trains of cars on the Ninth Avenue Elevated Railway in this city. Some weeks ago a train of eight cars was taken up a grade of nearly two per cent at a speed of seven miles and a half an hour. On several occasions a speed of thirty miles an hour, with three cars, has been reached. The regular train speed on the Ninth Avenue road is thirteen miles an hour, but with the electric motor no difficulty is found in maintaining a speed of fifteen miles an hour. A *Science* representative was one of a party, a few evenings ago, who were carried over the road from Fourteenth to Fiftieth Street at a speed approaching twenty miles an hour. The motion was smooth and easy, and there was nothing but the entire absence of smoke, smell, and cinders to indicate that the train was not drawn by an ordinary locomotive.

NOTES AND NEWS.

WE wish again to call attention to the monument for Audubon which it is proposed to erect over the place where he is buried. The authorities of Trinity Cemetery have changed the plot, and placed the remains in a well-constructed vault in one of the most conspicuous parts of the cemetery, and the committee in charge of the matter are anxious to have the monument erected as soon as the funds will justify it. Subscriptions are coming in very slowly. The committee have decided to distribute to each subscriber to the funds a copy of a portrait of Audubon which was painted by Cruikshank and engraved by Turnure. As this engraving is a copy of a very valuable and rare one, the committee hope that this will be an inducement to persons to subscribe.

John J. Audubon

— The American Society of Naturalists held in Baltimore, Dec. 27 and 28, one of its largest and most successful meetings. Methods of instructing large classes in botany were presented by Professors Goodale and Wilson, and in geology by Professors Niles and Williams. The society fully approved the excellent work of its committee on education, in paving the way for better instruction in the natural sciences in all grades of schools, especially the lower ones. Mr. J. E. Wolff showed a photographic method of class illustration, and Professor W. M. Davis explained a most interesting series of paper models, illustrating the development of certain topographic forms and their relation to base-levels of erosion. The society is composed largely of teachers, and desires to so arrange its meeting next year that the members may be able to attend the meetings of specialists held about the same time.

can institutions; and he has written one which will rank for years to come as the most thoroughgoing examination of them.

Professor Bryce's book will naturally be compared with the work of De Tocqueville, and it merits such comparison; yet it in some respects a greater book than that of the French student of our public life. If De Tocqueville made a philosophical examination of American institutions, Professor Bryce has made a scientific dissection of them. He enters into detail elaborately and accurately. He illustrates fully and freely. He rarely speculates. The book falls into three divisions, corresponding to the volumes as issued in the English edition. The first deals with our National Government; the second, with our State governments; and the third, with what, for want of a better term, we may call our politico-social institutions. Under the latter head are included the party system, public opinion, the bar and the bench, railroads, universities, and allied topics. The book is too large to be condensed, and too detailed to be described within the limits of a review: it must be read to be understood and appreciated, and it should be read by all classes of our intelligent citizens. It will serve to clarify the ideas of many people as to what our institutions really are, and how they work. It will make plain for the first time, to thousands of citizens who consider themselves intelligent, how public opinion is formed — or, rather, grows — in this country, how it finds expression, and how it rules. It will suggest to the careless democratic enthusiast certain points of weakness in our institutions, and certain dangers which we must sedulously strive to avoid.

Professor Bryce is unquestionably a democrat both by nature and by conviction, and an ardent admirer of democracy. This is perhaps the reason why some of the English critics have not been able to fully appreciate his work. It is the reason, also, which will serve to increase its popularity among our own people. It has been criticised abroad as too large, too diffuse, repetitious. It may be all of these; but these are merely defects of form, which the excellence of the matter more than counterbalances. That Professor Bryce's book will be widely read goes without saying. We can only add an expression of the hope that it may be intelligently read and pondered over; for it is a book that is meant to do good, and which will do good if it is read in the spirit in which it is written. We owe Professor Bryce a debt of gratitude for the time, the labor, and the patience that he has bestowed upon our national life. That his work will make us better known and better understood abroad, and better known and better understood by ourselves, is, we believe, a necessary result of its publication.

Aspects of Education. By OSCAR BROWNING, M.A. New York, Industr. Educ. Assoc. 16°.

The Slöjd in the Service of the School. By OTTO SALOMON. New York, Industr. Educ. Assoc. 16°.

Manual Training in Elementary Schools for Boys. Part. I. By A. SLUYS. New York, Industr. Educ. Assoc. 16°.

THESE are the three latest issues in the admirable series of educational monographs published by the Industrial Education Association of New York City, the growing circulation and general appreciation of which mark a gratifying public interest in matters pertaining to education. Mr. Browning's paper on "Aspects of Education" is known to readers of *Science*, inasmuch as its four chapters appeared in these columns some months ago. They are now rewritten and put together in a connected paper. As trenchant and accurate summaries of the movements apparent in modern educational thought, Mr. Browning's articles are not surpassed anywhere, and we are glad to find them reproduced in this permanent form.

Mr. Salomon, the author of the paper on "Slöjd," is well known as the director of the famous normal school at Nääs in Sweden. As the chief master of slöjd (sloyd), he is fully competent to treat it in its philosophic and pedagogic relations, as is done in the book before us. The translation by Dr. W. H. Carpenter of Columbia College is pleasantly done.

The third paper, by Professor Sluys of Brussels, is the most valuable and important yet issued, and we notice that Part II. of it will follow in March. Professor Sluys was the Belgian commissioner to

investigate and report on manual training, and his paper is full of citations of facts actually seen and known. The book is free from speculation, and is practical, complete, and unanswerable. We trust that it may fall under the eyes of such men as Superintendents Dickinson of Massachusetts, Marble of Worcester, White of Cincinnati, Gove of Denver, and Dr. Harris of Concord; for it will show them, impartially and dispassionately, how crude and unscientific their thinking on the subject of manual training is. We shall await the appearance of Part II. with interest.

The Roman Catholic Church and the School Question. By EDWIN D. MEAD. Boston, G. H. Ellis. 12°. 15 cents.

THE substance of this pamphlet consists of a lecture delivered before the Woman Suffrage League, Boston, but it has been expanded and revised for publication. It is a discussion of the question raised in Boston by the rejection, by the school committee, of Swinton's "History" as a text-book, the ground of the rejection being the opposition of the Catholics to Swinton's treatment of the sale of indulgences in the time of Luther. Mr. Mead here discusses the points at issue in an impartial spirit, and with a clear perception of the merits of the case. His style is not always so clear as might be wished, and shows marks of German influence; but, on the whole, the form and temper of the work are excellent. The address begins with a rebuke to the Protestants for some of the foolish things they have said during the late dispute, and intimates that their religion is not so decidedly superior to the Catholic as they are apt to suppose. But on the actual question at issue he takes strong ground against the Catholics, intimating pretty plainly that they opposed the use of Swinton's work for the sole reason that it tells the truth about the abuses once prevailing in their church. He condemns the parochial schools, and indeed private schools generally, holding that all American citizens ought to send their children to the schools maintained by the State. He then goes on to quote from certain Catholic school-books, showing how false to historical truth they are, not so much from actual misstatement as because of omissions, evasions, and exaggerated representations of what Catholics have done for the good of the world. To all persons interested in the questions at issue, and who realize the importance of correct teaching, the pamphlet will be of interest.

AMONG THE PUBLISHERS.

SOME of our readers may be interested in the second and third numbers of the new series of publications by the American Statistical Association. The former, by E. R. L. Gould, is on the subject of "Park Areas and Open Spaces in American and European Cities." Tables are given showing the number of open spaces in all the leading cities, with the amount of space and other items of interest. The author points out the importance of having many small breathing-spaces scattered about the city, especially in the quarters inhabited by the working-classes, and shows that many of our principal towns are deficient in this respect. It appears that some manufacturing cities have sadly failed of their duty, Pittsburgh having only one and a third acres of open space, and Scranton and some other towns none at all. Mr. Gould's general conclusion is, that the policy of American cities in this important matter has been very defective. The other paper is by Edward Clark Lunt, and is a "Key to the Publications of the United States Census." It gives a brief history of the taking of the various censuses, and then presents an epitome, or analysis, of all the census publications from 1790 to 1887. The different subjects dealt with in the census, such as population, races, agriculture, and so on, are treated separately; and under each head reference is made to the volume and page of each census report which gives information upon it. The United States census is so complicated a thing, and yet so important, that such help as Mr. Lunt gives must be of service to students of statistics.

— Professor Cleveland Abbe's "Treatise on Meteorological Apparatus and Methods" forms the second part of the "Annual Report of the Chief Signal Officer for the Year 1887," which has just been published. This admirable work is a handbook equal in value to Ferrel's theoretical meteorology and Hann's and Weicolf's cli-

matology, and supplements these works in a field in which a comprehensive and exhaustive guide to the student was most sorely needed. The plan of the book may be learned from the following passage of the preface: "A uniform thought has guided the arrangement of the chapters on the different instruments: namely, there is first given a general description of the object to be attained; second, a development of the formulæ for correcting the errors of the apparatus; and, finally, an indication of the refined methods of making standard determinations, to which all ordinary practical methods are to be considered as approximations." The volume treats of the measurements of atmospheric temperature and pressure, of the motion of the air, the measurement of aqueous vapor and of precipitation, while the subjects of optics, electricity, and actinometry remain to be presented in a subsequent volume.

— The lively discussion of the question of the influence of forests as regulators of rainfall and river-flow cannot fail to have a beneficial effect. Since the interesting discussion between Professor Fernow and Mr. Gannett which was published in a recent number of *Science* (xii. p. 242), Professor George F. Swain has given a comprehensive review of the subject in the *American Meteorological Journal*. The principal advance made in this investigation is the clearer understanding of the complexity of the phenomenon, and of the fact that the influence of forests cannot be the same in different climates, on plains, and on mountains, and that it depends on the genera and species composing the forest and on the covering of the ground in forests. While most American scientists hold that forests do not increase evaporation, Ebermayer and Woeikof claim the reverse. The latter even believes that this increase of evaporation is sufficient to effect an increase of cloudiness, and a consequent lowering of the temperature of summer. The only result that has so far been generally accepted is, that forests are regulators of the flow of rivers, on plains as well as in mountainous regions. This effect alone, setting aside the value of the wood, makes their protection of great economic importance.

— The number of the *American Journal of Psychology* just issued begins its second volume. The original articles that the first volume has contained demonstrate the profit of working the American psychological field, while the copious abstracts of current literature show both the activity of investigation elsewhere and the need of such a review as this department of the journal furnishes. The first article in the present number is on "Personal Equation," by E. C. Sanford, Ph.D. Astronomical methods early brought to light the vagaries of the human factor in observation, and since Bessel's discovery of personal equation the subject has received, at one time and another, the attention of many of the most distinguished astronomers. Their studies gave the impulse to the time-measurements in psychology that have been carried on with so much success by Wundt and others. Activity has also continued among the astronomers, and this paper is an attempt to turn to psychological account the results of their analysis and experimentation, and to bring together the results reached by both sorts of investigators. The history of personal equation (beginning with the notice of a difference in the observations of Maskelyne and Kinnebrook), and of the methods from time to time applied for measuring or avoiding it, makes an interesting episode in the history of science. In a second article the author proposes to treat the variations of personal equation, and discuss the theories of its origin. The second paper is the first section of an historical and experimental study of memory, by W. H. Burnham, Ph.D. The growth of the psychology of memory is traced from the earliest Greeks to Kant. In Plato are found the beginnings of that transcendental view of memory that make it a function of the soul independent of the body. The Neoplatonists St. Augustine and Leibnitz, neglecting individual variations, are of this party. Aristotle, on the other hand, who wrote a monograph on memory and developed the doctrine of association, is the father of Aquinas, Hobbes, Condillac, Bonnet, Hartley, and all those that see in memory only the traces of former sensations whose basis is in the end physiological. The special views of these and other philosophers, and their contributions to the theory of memory, are briefly stated by the author, as a basis, we suppose, for the presentation of modern views and the experimental treatment. It is true, that, while physiology and biology can now de-

clare that memory is in their field as well as in that of psychology, the germs of modern theories are to be found among the writings considered by Dr. Burnham. The practical side of memory receives attention in a short section on mnemonic systems. Dr. Mary Putnam-Jacobi contributes a paper on "The Place for the Study of Language in a Curriculum of Education." The first section attacks this much-debated question from a new standpoint; namely, that of cerebral physiology. The relations of language and cortical excitation are expounded at length, and the conclusion reached "that speech implies a more extensive excitation of the brain than does any action performed without speech." The acquisition of language in general has a distinct educating effect: it cultivates abstraction, and generally prepares the mind for its work. The acquisition of foreign languages in addition to the mother-tongue further complicates, extends, and refines the cerebro-mental processes. A comparison of mathematics and language shows the former to be valuable for constructing the syllogism, the latter for establishing the premises; in other words, for the details of every-day life. Between the study of things (that is, physical science) and language there is no antagonism. Language, properly studied, is rather a propædeutic to science. Between the time when the child is busy in collecting the sense-images of common things, and the time when he can return to them prepared for a genuine scientific study of them, is the period in which he should devote himself to language; not in the rote fashion, of course, but by a graded study, in which the scientific faculties of observation and induction are exercised on materials more accessible and more comprehensible than those of the distinctive sciences. By the age of sixteen the most of this work should be completed and out of the way; and, though language-study is not then to be entirely given up, the field will be free for other disciplines. The last part of the paper is devoted to practical suggestions for this kind of language-teaching. The reviews of psychological literature are, as before, one of the most important features of the journal. Nowhere else in English is it possible to secure such a conspectus of what is doing in the fields from which the new psychology draws its materials.

— On and after Jan. 1, 1889, the publication office of the Leonard Scott Publication Company will be transferred from Philadelphia to New York City, and the *Nineteenth Century*, the *Contemporary Review*, the *Fortnightly Review*, the *Westminster Review*, the *Edinburgh Review*, the *Quarterly Review*, the *Scottish Review*, *Blackwood's Magazine*, *American Naturalist*, and *Shakespeareana* will hereafter be issued from New York City. This change has been made to insure an earlier issue of these periodicals by the greater facilities thus secured for the importation of original sheets.

— The opening essay in the *Quarterly Journal of Economics* is by E. B. Andrews, on the subject of "Trusts according to Official Investigation." The facts presented are taken from reports of legislative committees and other governmental authorities, the object of the writer being to show what these organizations really are. Some difficulty was found by the investigating committees in getting at the exact truth on certain points, owing to the unwillingness of the witnesses to reveal it; but in the main the organization and working of trusts have been pretty clearly made known, and the leading facts relating to them are here set forth. The principal organizations dealt with are the Standard Oil Trust, the Sugar Trust, the Cottonseed-Oil Trust, and the Whiskey Trust; and on all of these Mr. Andrews's paper conveys a large amount of interesting information. With regard to the economic influence of trusts, the writer expresses himself guardedly; but he evidently thinks that they need watching. Professor Hadley discusses the subject of "Railroad Business under the Interstate Commerce Act," and shows that since the act went into operation the value of railroad property has depreciated twenty per cent. This he attributes to the prohibition of pooling, which prevents the maintenance of paying rates by the agreement between the companies; and he believes that a change in this provision of the law will eventually have to be made. Besides these two leading papers, the journal contains one by F. Y. Edgeworth on the question of whether gold has risen in value in recent years, on which, however, he reaches no definite conclusion. Mr. Simon N. Patten also has a

paper on "The Fundamental Idea of Capital," holding that capital is "every thing on which, labor being expended before the produce is wanted, the return will be increased beyond what it would be if the same labor had been exerted contemporaneously." The paper is of a rambling character, and the author's view is not presented with clearness. The journal contains the usual variety of miscellaneous matter, and closes with the first part of a paper on "Italian Finance," by A. B. Houghton, comment on which may be deferred till the appearance of the remainder.

— *The Open Court* for last week contains two articles upon the life and work of the late Mr. Courtlandt Palmer, the founder of the Nineteenth Century Club of New York City, entitled "The Universal Faith, an Address upon Mr. Courtlandt Palmer," by T. B. Wakeman; and "The Founder of the Nineteenth Century Club," by Moncure D. Conway. Professor Georg von Gizycki of Berlin, Germany, has two articles in *The Open Court* of Dec. 27 and Jan. 3, entitled "Death and Life," and "The Conservation of Energy in the Moral World."

— Mr. Daniel Greenleaf Thompson, the new president of the Nineteenth Century Club, and author of "The Problem of Evil," is about to publish an inquiry into the fundamental principles of social ethics and a discussion of the trend of social evolution. "Social Progress" is the title of his book, which will be issued shortly by Longmans, Green, & Co., both in London and New York. Mr. Thompson concludes by declaring his belief that social progress can be attained only through the perfection of social liberty.

— The first number (January) of the *Cumberland Presbyterian Review*—a quarterly magazine, devoted to theology, and the discussion of current religious, literary, and scientific topics, and questions connected with church-work and moral reforms, with J. M. Howard, D.D., as editor, and D. M. Harris, D.D., M. B. De Witt, D.D., and W. J. Darby, D.D., as associate editors—contains "Physical Basis of Moral Life," by President A. B. Miller of Waynesburg College; "The Family of God," by the Rev. W. H. Black, St. Louis, Mo.; "The Mosaic Doctrines of Death and After-Death," by Professor R. V. Foster of Cumberland University; "Preaching without Notes," by Rev. W. S. Danley, Lincoln, Ill.; "Charles Darwin," by Professor J. I. D. Hinds of Cumberland University; "The Pastor Getting Hold and Holding On," by the Rev. W. J. Darby, Evansville, Ind.; "The Philosophy of Missions," by Rev. D. E. Bushnell, Waynesburg, Penn.; "Our Senses: How We Use Them, and What They Tell Us," by John J. Tigert of Vanderbilt University; "The Decay of Christian Citizenship," by T. M. Hurst, Nashville, Tenn.; "Spirituality in the Church," by the Rev. P. Margeson, Marshall, Mo.; and "The Bible and Utility," by the Rev. J. D. Gold, Waukon, Io.; besides editorials, notes, and reviews of books. Single copies, per year, \$2.50; in clubs of five or more, \$2. Subscriptions should be sent to John D. Wilson, agent, 331 Church Street, Nashville, Tenn.

— Cassell & Co. will publish at once the fourteenth and concluding volume of the "Encyclopædic Dictionary." This work has been in preparation for nearly seventeen years, and extends to no less than 5,629 pages.

— D. Appleton & Co. publish a translation of Karl Marx's important work on "Capital," edited by Frederick Engels; also, in their Town and Country Library, "A Fair Emigrant," a story by Rosa Mulholland. Hereafter the volumes in this library will be put up in a neat cloth binding at 75 cents per volume.

— D. C. Heath & Co. publish for school use "Selected Poems of Wordsworth," collected and edited by A. J. George. The volume will contain lyrics, sonnets, odes, and narrative poems such as are requisite for a thorough understanding of the genius of the great poet. With the exception of the sonnets, which are grouped according to subjects, they will be arranged in chronological order. In the matter of annotation, only such material will be furnished as the pupil would not be likely to find elsewhere.

— *The Publishers' Weekly* states that A. D. F. Randolph & Co. have issued an edition of "The Thumb Bible," by John Taylor (born in 1580, died in 1654), commonly called the "Water-Poet."

Taylor, after fulfilling his apprenticeship to a waterman, seems to have served in the fleet under the Earl of Essex. Afterward he took up the trade of a waterman, and for a time was an excise collector. He was not really a poet, although he could string rhymes together with facility. At the approach of the civil war, he retired to Oxford, and was a publican. His sympathies were wholly with the Royalists; and when the town surrendered, he returned to London, and there kept a public-house. Here he died. He published "Verbum Sempereternum" (an epitome of the Old Testament in verse), dedicated to Charles I.; "Salvator Mundi" (an epitome of the New Testament in verse). These two were published in one volume in 1693, and dedicated to the Duke of Gloucester, etc., under the title of "Verbum Sempiternum," being an epitome of the Bible, termed from its size "The Thumb Bible." It was reprinted in 1849 by Longman & Co., London, and again during the present year by Hodder & Stoughton.

— D. Appleton & Co. have now ready the first volume of "An Illustrated Encyclopædic Medical Dictionary," to be completed in four volumes, compiled under the direction of Dr. Frank P. Foster, editor of the *New York Medical Journal*, with the collaboration of a dozen of the leading physicians of America. It is to be a dictionary of technical terms used by writers on medicine, physics, botany, chemistry, zoology, and other collateral sciences in the Latin, English, French, and German languages. Accuracy, convenience of arrangement, and comprehensiveness are guaranteed by the practical scholars in charge of this Herculean undertaking.

— "The literary executor of Theodore Parker," says the *Boston Transcript*, "is preparing a new edition of his 'Historic Americans,' in which there will be added to Franklin, Washington, John Adams, and Jefferson, Parker's sketches of John Quincy Adams, Dr. Channing, and Webster. The volume will be twice as large as that edited by Octavius B. Frothingham, in 1870, and will contain a larger introduction and more frequent notes. Each biography will be short, not running beyond seventy-five pages, and these will contain the verdict of Parker on the life, character, and results of all of these great Americans, whose career covers the period from 1740 to 1850, or more than a century. The volume will be followed next summer by Parker's autobiography, — a work essentially new, though made up largely from materials published by himself and others from 1850 to 1875. Many passages from the diary and letters will be given, however, which have never been published, relating to Parker's acquaintance with Alcott, Emerson, Margaret Fuller, Bettine Brentano, Garrison, Wendell Phillips, and other contemporaries."

— Sampson Low & Co. have in preparation "A History of English Bookselling," by William Roberts.

— A work to be issued by the Cambridge University Press is "The Literary Remains of Albrecht Dürer," by W. M. Conway. The volume will contain transcripts from the British Museum manuscripts, and it will be illustrated.

— "The Villon Society," says the *Academy*, "will shortly issue an addendum to their edition of 'The Thousand Nights and One Night.' The new volume will contain the stories of Aladdin and Zeyn el Asnam, translated from the newly discovered Arabic text by Mr. John Payne."

— The Geographical Society of St. Petersburg has just issued a superb edition of the last work of Gen. Prjevalsky, entitled "From Kiakhta to the Sources of the Yellow River," an exploration of northern Thibet and the route across the basin of Tarim by Lob Nor. The book gives portraits of the author and his companions, and many maps and illustrations. Like all work done by this lamented author, it is exhaustive and scholarly, and a convincing proof that the untimely death of the writer is a great loss to Russian science.

— The readers of *The Popular Science Monthly* will be glad to learn that Dr. Andrew D. White's "New Chapters in the Warfare of Science" are to be resumed in the February number. Dr. White has devoted several years to the investigation of this subject, and is now in Europe making an examination of the libraries there for additional material, which shall enable him to continue his ac-

count of the persistent dominance of delusion in the human mind. The chapter immediately forthcoming will treat of "Demoniac Possession and Insanity."

— The way the Interstate Commerce Law looks from the side of the railroads will be shown in the February *Popular Science Monthly*, by Mr. Appleton Morgan, in a vigorous article entitled "The Political Control of Railways: is it Confiscation?" Mr. Morgan maintains that this act, by prohibiting pools, nullifies its other prohibition of discriminations; in fact, increases discrimination, when the whole people is regarded.

— "The Story of a School" is the title of an article by the late Professor James Johannot, to appear in the February *Popular Science Monthly*. It is an account of the success achieved in conducting a normal school according to natural methods, arranging the subjects of study in their order of dependence, teaching science by observation, language by using language, mental and moral philosophy objectively without books, and with no marking system, rules of discipline, or distinctive religious exercises.

— *The American Queen*, a monthly magazine for the home, is published by the First National Publishing Company (John C. Rand, president), 131 Devonshire Street, Boston.

— We have received from F. W. Christern & Co. (New York) the first number of *L'Exposition de Paris* of 1889. It contains, among other things, a large bird's-eye view of the exposition grounds and buildings, pictures of the chief and assistant engineers and architects, including M. Eiffel, general and detail views of the 300-metre tower now being erected by the latter gentleman, and a prospectus of the exposition. Forty numbers of the publication will be issued during the progress of the exposition, at ten cents a copy.

— An extra December number of the Riverside Literature Series (Houghton, Mifflin, & Co.) is devoted to "Dialogues and Scenes from the Writings of Harriet Beecher Stowe," arranged for reading-exercises and dramatic representation, by Emily Weaver. Care has been taken to adhere to the original text as closely as possible; and, to make the dialogue clear and to explain the action, explanatory passages from the books in which the dialogue occurs are added from time to time. The dialogues are taken from "Uncle Tom's Cabin," "Old Town Folks," and "The Minister's Wooing."

— In a copiously illustrated article in *Frank Leslie's Illustrated Monthly* for January, Lieut. F. S. Bassett, U.S.N., traces the evolution of the rudder, from the primitive paddle with which the savage both propels and guides his dug-out or birch-bark canoe, to the modern steam or hydraulic steering-gear of the great ocean steamships. The illustrations, which are drawn from early monuments and coins, and mediæval frescos and paintings, show the change in method of steering, from that in which the blade of the oar or paddle is moved bodily through the water in a nearly horizontal plane, to that in which the vertically placed successor to the oar-blade, the rudder, is merely turned upon its axis. An interesting fact mentioned in the article is that one of the most recent improvements in steering apparatus is a reversion, on a higher plane, to the most primitive method, a swinging propeller both driving and guiding the vessel, as did the paddle in the hands of the savage. An article somewhat similar in nature to that of Lieut. Bassett's, though more limited in scope, is published as a supplement to *Harper's Weekly* of Jan. 5. It is entitled "The Evolution of the Ferry-Boat," and is from the pen of S. Bayard Dod. Though dealing only with the ferries and ferry-boats of New York, it contains much to interest the general reader. Beginning with the first licensed ferry on the North River, that between New York and Communipaw, in 1661, when the fare was "six stivers a head Wampum for every passenger," and the boat was propelled by oars or sails, Mr. Dod follows the growth of the ferries down to the "horse" stage, when the boats were propelled by paddle-wheels actuated by horse-power, and then to the introduction and development of steam ferry-boats, ending with a description of the latest triumph of ferry-boat architecture, the "Bergen,"— a steel boat, with fifteen water-tight compartments, and a propeller at either end, to take the place of the paddle-wheels which have prevailed heretofore in such boats. Either a slip of the

pen or a printer's error makes Mr. Dod say that the walking-beam low-pressure engines in general use "have gradually increased in size, from 25-foot diameter of cylinder with 5-foot stroke, to 46 and 50 inch cylinder with 10-foot stroke."

— Professor J. H. Gore of the Columbian University has in preparation a bibliography of geodesy. During two trips to Europe he has collected about seven thousand titles, having examined nearly every large library except that at St. Petersburg. He begins with the first effort to ascertain the shape of the earth by triangulation in the seventeenth century. The work will be published soon by the Coast Survey. Professor Gore is trying to make his service complete by personal application for data, he having written to all astronomers and other mathematicians in the world whose addresses he could obtain. He asks *Science* to say that the co-operation of its readers is desired.

— Dr. C. A. White has just prepared a bulletin for the Geological Survey, on "The Permian of Texas," adducing some facts not hitherto published, in recognition of the Permian in North America, and exhibiting some fossil forms not hitherto known to exist on this continent, and a commingling of paleozoic and mesozoic types similar to those discovered by Waagen in the Salt Range of India.

— The *London Globe* of Dec. 4 describes a new plan for the lending of books. The circulating library is now an important element in English life, and, widely spread as are its ramifications, it is possible seemingly to extend them even further. The experiment, at any rate, is to be made in Austria-Hungary and on the railways there. In England Messrs. Smith & Sons have a circulating library in connection with their book-stalls, but they do not lend books for perusal on the journey only, charging a fee and taking the volumes back again at "the other end." Yet this is precisely what the Austrian firm propose to do. The traveller will be required to pay a deposit which shall cover the price of the book lent, and also a small charge, amounting to about threepence in English money. He will choose a volume on starting, and return it on arrival at his destination, where he will receive the sum deposited. No doubt the project will succeed, if the supply of books is found satisfactory by the voyager.

— From the *Pall Mall Gazette* we learn that Miss von Hoerschelmann's two-volume "Kulturgeschichtlicher Cicerone für Italien-Reisende" has had the rare distinction in Germany of being by special permission dedicated to the Empress Frederick, before whom and the Emperor the lady has repeatedly lectured. Like every thing else in Germany, the dedication of a literary work to a member of the imperial family is connected with an incredible amount of red tape. There is a codex in the laws relating to the imperial household according to which no scientific work may be dedicated to any member of the imperial family unless it comes up to a certain standard. A number of *savants* "sit upon" each work of this kind, and determine whether the dedication is to be or not to be. One of the conditions is that the work shall contain views or discoveries hitherto not dealt with. Miss von Hoerschelmann's Cicerone could naturally not lay claim to this distinction, and it was owing to a special interference of the Empress Frederick that her two volumes passed the censor and were dedicated to her Majesty.

— The Aldine Book Publishing Company state that they have sold nearly 10,000 copies of their "Europe Illustrated."

— The Library Bureau, Boston, announces to subscribers to the "Decimal Classification," that, after many unforeseen delays, the complete tables and index of 20,000 entries was printed last month, and will be in from the bindery this week. The regular edition, containing the introduction, cannot be had from the bindery till after the holidays, possibly by Jan. 30. Those in special haste may obtain now the tables and index bound, and in January the introduction in pamphlet form.

— According to *The Publishers' Weekly*, Col. Wright, the commissioner of labor, expects to send two volumes to Congress before the present session closes. The first will be the fourth annual report of the Labor Bureau, and will be devoted to the working-women in the great cities. The other volume will be the report

on divorces and divorce laws, for which a special appropriation was made by Congress. The records of 2,700 courts have been examined; and the volume will give, in classified form, the number of divorces, with causes, number of children, when divorced, and other accessible information. The agents of the Department of Labor are now at work on the fifth annual report, which will not be ready for a year yet, on the wages of railroad-men.

—“Mr. B. F. Stevens, 4 Trafalgar Square, London, has been for some years at work on indexes to the manuscripts relating to American affairs between 1763 and 1783 preserved in European archives. The United States Government urged the purchase of these indexes, and also the obtaining of transcripts of the documents themselves. Congress has, however, made no grant for the purpose, and Mr. Stevens therefore boldly proposes to publish photographic facsimiles of the documents, provided he can obtain a hundred subscribers to begin with. Each document will be accompanied by a statement of its *provenance*, and of any variations to be found in other copies, if such exist; and a translation will be added when the original is not in English. Mr. Stevens calculates that when he has once fairly started he will be able to publish monthly two volumes of some 500 pages each, and he asks \$100 for every five volumes. A copious index will be published to every twenty-four volumes, and the price of it will be \$20. Mr. Stevens thinks that this valuable series of facsimiles will ultimately fill 100 volumes.”

—Columbian University has announced a unique course of lectures for the coming months, on “The Human Emotions from an Anthropological and Psychological Point of View.”

—At the meeting of the Philosophical Society on Jan. 5, obituary notices were made of Peter Parker, E. B. Elliott, F. V. Hayden, Roland D. Irving, Thomas Hampson, and Emil Bessels; and Mr. Bailey Willis read a paper on “The Mechanism of the Overthrust Fault.”

LETTERS TO THE EDITOR.

*.*Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith.
Twenty copies of the number containing his communication will be furnished free to any correspondent on request.

Two Discoveries in Human Osteology by the Hemenway Expedition.

I HAVE the honor of enclosing to you a letter handed me by my friend Professor Edward S. Morse, who deems the matter therein discussed by Mr. Cushing of such importance as to merit prompt announcement in your journal.

First, however, I will ask leave to mention briefly another important discovery made during the researches of the Hemenway Expedition in the Salado and Gila valleys in southern Arizona last winter and spring. In the summer of 1887 Mr. Cushing, the director of the expedition, was dangerously ill at Camp Hemenway, on the site of the prehistoric city of Los Muertos. Through the kindness of Secretary Endicott and Surgeon J. S. Billings (the director of the Army Medical Museum at Washington), Surgeon Washington Matthews (the curator of the museum and an intimate friend of Mr. Cushing) was ordered to Arizona to his relief and assistance. Dr. Matthews, whose arrival at Camp Hemenway was just in time to save Mr. Cushing's life, was so much impressed with the character of the ancient skeletons there exhumed, that, as an anthropologist, he perceived that it would be of immense scientific value to have them preserved in the most careful manner possible. On his return to Washington, he represented the matter to Dr. Billings, who at once detailed Dr. J. L. Wortman, the talented comparative anatomist of the museum, to assist the expedition in properly exhuming and preserving the skeletons. It is a notable fact, that, with few exceptions, the skeletons in the various museums of the world have been carelessly collected, and are therefore worthless in the study of certain features: therefore the importance of having this work proceed under the supervision of two such men as Drs. Wortman and ten Kate, the latter the anthropologist of the expedition, may be perceived. Fortunately the expedition had also three or four Mexican workmen of such native intelligence, that, under the training of the two doctors, they became highly expert in the recovery of the skeletons, complete in every detail; the great

age of the remains rendering them very fragile, and demanding, therefore, extremely careful manipulation.

Early in the course of the work, Dr. Wortman observed indications of a remarkable anatomical peculiarity in the remains. Calling the attention of Dr. ten Kate to the fact, together the two pursued the investigation of the same, and all subsequent observations thoroughly confirmed their first inference. This fact was, that in this race the hyoid arch, or basi-hyoid, which together with the stylo-hyoid forms the bony structure at the base of the tongue, was not in the adult co-ossified, the three small bones forming the arch remaining free through life; the only exception being in the case of skeletons bearing marks of bone-disease, exhibited in the co-ossification of various articulations, in which cases the bones of the basi-hyoid were apt to be ankylosed, though occasionally on one side only. The strongest evidence was that exhibited by the skeletons of old persons, which proved no exception to the general rule of this observation.

This peculiarity was contrary to all the former experience and studies of the two observers, and it indicated the discovery of a pronounced racial character; for, according to what they had hitherto learned concerning this feature, the ankylosis of the basi-hyoid took place either at or before middle life.

Consulting the literature of the subject, it was found that both the English and French anatomical authorities concurred in this view, while the German authorities held that the several bones of the arch remained free, ankylosis taking place only exceptionally or in extreme age. It was inferred that the German view was either based upon insufficient evidence, the conclusion being drawn perhaps only from the anatomy of young persons, or that the anatomy of the German race differed in this respect from that of the English and French.

These observations were embodied in a brief preliminary paper by Drs. Wortman and ten Kate, and communicated to the International Congress of Americanists held in Berlin last October, at which Professor Morse and I had the honor of representing the Hemenway Expedition. The paper was read to the congress by Professor Morse, who illustrated it with blackboard-drawings. The subject occasioned much interest, for it was felt that it would prove to be of extreme importance should it turn out to be a peculiar feature of the aboriginal race of the American continent, as was indicated. Subsequent examinations of a large number of skeletons exhumed from ancient ruins during the excavations of the Hemenway Expedition at Zuñi, where it is now at work, have uniformly supported this view; and while we were in Berlin a Pe-

ruvian mummy was placed at the disposal of Professor Morse by Dr. Wilhelm Reiss, the learned president of the congress, and the discoverer, in association with Dr. Stübel, of the famous Ancon antiquities. An examination of this mummy, which was that of an elderly person, showed that the elements of the hyoid arch were free.

When the attention of Professor Virchow was called to the subject by Professor Morse, that eminent anatomist said that the question had apparently been entirely neglected. He was inclined, however, to support the correctness of the view advanced by the German authorities, and regard the co-ossification of the hyoid arch as occurring only under abnormal or pathological conditions.

Returning home by way of London, while visiting the British Museum of Natural History, we had the good fortune to meet the eminent mammalogist, Professor Flower. When we called his attention to the subject, he expressed the liveliest interest, saying that the observation was entirely new, the separation of the bones of the basi-hyoid being wholly contrary to any thing observed in his own large experience. He had taken the pains of making careful observations of this feature, and had made preparations of full sets of the *os hyoides* both in man and the lower mammalia. In man he had found that co-ossification took place at maturity, and in proof he called attention to a complete series of British hyoids which he had prepared for the College of Physicians and Surgeons. Therefore he would regard this observation of Drs. Wortman and ten Kate as indicating a very important discovery. The collection of human hyoids at the College of Physicians and Surgeons was inspected by Professor Morse, who found it prepared with the skill and knowledge for which Professor Flower is famous. Every specimen, when after maturity, was co-ossified.

Under a co-operative agreement made at the time between the Army Medical Museum and the Hemenway Expedition, the skeletons exhumed from the ancient cities in southern Arizona have been deposited with the former institution; and Dr. Billings is so impressed with the importance of the question, that Drs. Matthews and Wortman have been requested to make it the subject of an exhaustive research. In this work they, with their assistants, are now engaged, and have been supplied with an abundance of material from various races, in order to make the needed comparative observations. A full report thereon will be forthcoming in due time, but it may already be stated that the investigations have been advanced to a stage that fully confirms the opinion originally formed by the observers,—that in the peculiarities of the *os hyoides* is to be found the most distinctive racial character yet observed in human osseous anatomy. Its value in the determination of vexed questions can hardly yet be estimated, but it will undoubtedly prove of great anthropological service.

Dr. Wortman inclines to the view that it will be found that language plays a leading part in determining the form of this feature. The language of the American Indians is such that it requires but slight effort in utterance. An Indian can talk for hours at a stretch with little fatigue, and even a superficial observer will notice the restrained quality of the voice, the tones not being projected as with us. Now, the development of ankylosis being held to proceed from exercise, or irritation of the bone, from muscular action or otherwise, it is evident that in a language like that of the Indians there would be less muscular action exerted upon the hyoid arch than in one like ours, where more force is used, and therefore the co-ossification of the parts would be less encouraged. This view of Dr. Wortman's obtains support in observations made by Mr. Cushing at Zuñi, where he finds that the voices of those who are afflicted with bone-disease differ in quality from those of the tribe at large, and infers that their difference may be due to co-ossification of the hyoid brought about by the disease.

With the foregoing remarks, I hereby submit Mr. Cushing's letter concerning the other important osteological observation mentioned in the beginning.

SYLVESTER BAXTER,
Sec'y Hemenway Expedition.

OLD FARM, MILTON, MASS.,
Nov. 9, 1888.

My dear Morse,—Last evening I chanced to tell Mrs. Hemenway something about the observations we made on the distorted skulls of

Los Muertos and Halonawan. She was greatly interested, especially in what Baxter had to say relative to Dr. Virchow's paper before the recent congress, on, I think, deformed American crania. She wished me to write a brief statement of the case and send it to you, as of possible use to Drs. Virchow and Bastian.

While our excavations were in progress, I observed, by keeping close watch over the disinterments, that all, or nearly all, skulls occurring in earth sepulchres, were apparently deformed by artificial means. From the fact, however, that skulls taken from stone graves or cists, or from other sorts of tombs wherein they had been fairly protected, were uniformly and regularly brachycephalic, and showed no other sign of distortion than the occipital flattening from the cradle-board, I was led to infer that those from the earth sepulchres had been deformed by accident; that is, by post-mortem influences.

Subsequent observations, in all of which I was confirmed by Dr. ten Kate, indicated the entire correctness of this inference. For example: no general rule of cranial disfiguration (always with the above instanced exception) was found to prevail. On the contrary, the disfigurations seemed to depend largely, if not wholly, on the positions of the skulls. When the latter were lying on their sides in the graves, at an angle of, say, forty-five degrees, one side of the coronal region would be depressed, and sometimes the face, even, would be obliquely distorted, as in Fig. 1 of the accompanying slips. Again, when the skeleton was lying on its back, with head elevated, the crown would be greatly depressed, as in Fig. 2; or, if the head happened to be less elevated, face partially upturned, the frontal region was invariably more or less flattened and broadened, as in Fig. 3; or, if, finally, the head chanced (face still upward) to be greatly depressed, the parietal region was flattened, throwing the frontal forward sometimes to an extraordinary degree, as in Fig. 4.

Perhaps the most extreme of these cases of post-mortem distortions of skulls were those which, belonging to skeletons of persons who had been buried on their sides, were so regularly flattened laterally that they seemed unmistakably to belong to the dolichocephalic class, as in Fig. 5. In fact, the only examples of "long-headed" skulls found during our researches, in either the north or the south (among the ancient ruins, that is), were so plainly distorted by this post-mortem pressure, that they made no exception to the rule established by Dr. ten Kate, that the Pueblo or Aridian was a short-headed race.

All this is simply due to the practice of blanket-burial. The skulls, being unprotected during the earlier years of burial, are, by the pressure of the earth, gradually deformed,—so gradually, indeed, that they neither crack, nor do the sutures part. The deformities are therefore in no wise distinguishable, after the specimen is removed from its original resting-place, from those produced by art. We are now, therefore, forced to note, in collecting our crania, their relative positions in the earth sepulchres very carefully.

I sincerely hope this may prove useful to Drs. Bastian and Virchow, or at least of some interest to them and the many other gentlemen who were so courteous to you and Mr. Baxter.

Faithfully yours,

FRANK HAMILTON CUSHING.

The Julien Electric Traction System.

IN the opening pages of your journal of Dec. 21, 1888, a description is given of the Haus Electric Railway, and comparisons are made between that system and other systems of electric traction. A paragraph is devoted to pointing out what the writer claims to be the defects of the storage-battery system.

It is very much to be deplored that some electrical railway companies attempt to raise their own systems in the public estimation by crying down other systems. What is still more deplorable is, that, in attempting to do this, they are not always friends to truth. There could be no better proof of this than the paragraph I have above referred to on the storage-battery system.

The writer admits that the storage-battery plan "would seem to be the ideal system," for the reason, among others, that "it dispenses with the necessity of a continuous conductor, the electrical generator and motive power are all contained within the car, and there is apparently an entire absence of any possibility of danger to the passengers." The writer goes on to say that "these favorable anticipations would be justified were it once demonstrated that a storage-battery had been devised that was economical of power, of reasonable weight, and durable in service." The writer

then goes on to say that "the best storage-battery that has been devised is very wasteful as a source of motive power, yielding at most but forty per cent of the power applied." Now, nothing could be further from the truth than this statement. There is probably not a storage-battery at present on the market that will not yield eighty per cent of the power applied. Almost any person of electrical knowledge and experience knows this to be a fact; and, if further proof be necessary, it will afford me much pleasure to have you send an expert, at my expense, to the electric station of the Julien Electric Traction Company, 85th Street and Madison Avenue, this city, to verify for himself the truth of this statement. He can there see for himself the number of watts the battery receives from the dynamo; and, if the battery does not discharge over eighty per cent of the watts so received, you are welcome to publish the fact to the world.

The next objection the writer raises to the storage-battery system is, that it is "excessively heavy and bulky, making it necessary to carry about three times the load of an ordinary car." Now, "the load of an ordinary car" (16-foot car) is 3 tons: consequently a storage-battery car would have to carry 9 tons of battery, if we are to believe the writer. Now, Car No. 3 of the Julien Electric Traction Company, at present running on Fourth and Madison Avenues in this city, carries just 120 elements, or cells, of battery, each element weighing exactly 27 pounds, or 3,240 pounds; or, with the trays and containing-boxes, 3,600 pounds,—a little over 1½ tons, instead of 9 tons, as the writer would have us believe. Let me add, in connection with the weight of a storage-battery car, what every engineer knows, that in a locomotive (which the storage-battery car is), to have adhesion, you must have weight.

The 120 cells above referred to contain 52 horse-power hours, and will carry that car over the streets of New York, without being recharged, for a distance of at least thirty-six miles, and carrying over four hundred passengers in all. If the Hauss Electric Railway is now doing equally acceptable and economical work, it would be very interesting for the public to know it. The writer omitted, by the way, to state where the Hauss electric system may be seen, and what practical experience, if any, it has had.

The writer goes on to say that the storage-battery system requires a special car to be built, to provide the necessary space beneath the seats to receive the battery. This is equally untrue. Car No. 3, above referred to, is an old horse-car, and was altered at an expense of about two hundred and fifty dollars for its present purpose. The alteration required is the lifting of the car-body, some five inches above its present position.

The next objection the writer has to the storage-battery is, that it "has a life of only two years of constant service, and it is subject to the danger of short-circuiting, which at once destroys its usefulness." The remark as to short-circuiting is very amusing. Am I to understand that the motors constructed by the Hauss Electric Railway (if they do actually construct any) are not subject to the danger of short-circuiting? If so, we must assume that their usefulness is destroyed. Now, we all know that the experience of every electric railway in the country is that the electric-railway motor has the same tendency to short-circuit that the most peevish mule has to kick. If the short-circuited motors of 1888 were made a pile of, we should not need to go to Egypt to see a pyramid. The fact is, that, since the fifteenth day of September last, up to the present moment, we have not short-circuited a battery in our street-car service, although our cars have run in that time in passenger-service some seven thousand miles. This storage-battery short-circuiting is a thing of the past. The cells are at present so connected that short-circuiting is impossible; for the connector would be blown out of position by an excessive current, and thus save the battery. We should be pleased to have you verify this at our station in this city. The writer gives our battery "only two years of constant service." We thank him for that concession, for we only ask six months' constant service in order to compete with the cost of horse-traction. He probably forgets that the material in the battery is not destroyed when the "usefulness" of the battery ends, but is again made over into battery by a process so cheap as to compete favorably with the maintenance of horses.

One word more, Mr. Editor, and I have done. Our 18-foot cars,

Nos. 1 and 2, now in the service of the Fourth and Madison Avenue lines, in this city, run from 86th Street and Madison Avenue to the Post-Office, and back,—a distance of twelve miles,—on an expenditure of less than fifteen horse-power hours of energy, and frequently carry over two hundred passengers on the round trip. This seems almost too good to be true; but you would do us a favor by inspecting the records at our station, and verifying this statement for yourself. With storage-battery traction there can be no mistaking the amount of energy expended; for we know the number of horse-power hours that are put into the battery, and of course the number of miles such charge will carry the car. Now, for the information of the public, we think it but fair that the Hauss Electric Railway should tell us how far fifteen electrical horse-power hours has carried one of their cars. The comparison would be very interesting.

New York, Jan. 5.

The Soaring of Birds.

IN a recent number of *Science* (xii. p. 267) I notice an article under the above heading. It seems to me that we have not yet got to the bottom of the matter, and that the true explanation of the phenomenon is still simpler. Imagine a piece of paper floating in the air. The wind takes it, and carries it along horizontally with its own velocity. After it has assumed the velocity of the wind, there is but one force acting on it; namely, the vertical one due to its own weight. Imagine now a bird under the same circumstances. Instead of travelling with the wind, as everybody who has watched a

soaring bird knows, he travels round and round in circles, each one a little higher than the last, and each one a little farther along in the direction towards which the wind is blowing. Now, when he travels with the wind, he attains nearly its velocity, and then turns and travels against it, rising rapidly at the same time, till he is nearly stationary, or perhaps is even going a little backwards, relatively to the ground. He then turns and travels with the wind again, either moving along horizontally, or perhaps dropping somewhat nearer the earth, until he attains his original velocity, when the cycle is repeated. Comparing his motion with that of the paper, we find that he does not move along so fast: there must, therefore, be some compensating advantage obtained, in order to use up the surplus energy derived from the wind.

In the above figure let *H* represent the direction of the wind, and *A* the position of the bird. Let *AB* represent the force due to his weight, and *AD* the mean force exerted on him by the wind, owing to the fact that he does not move along as fast as the surrounding air. Combining these, we get the resultant force *AC* acting upon the bird. Now construct the plane *EF* perpendicular to the line *AC*. The bird may then move anywhere in this plane without losing energy. He cannot move to the right of it, but he may move to the left, and thus gain energy. Practically he will move in a spiral about the line *AG*, thus slowly dropping from the plane

EF, but gaining enough energy by that means to make up for that lost by friction with the air. He will thus gradually rise from the earth, and at the same time drift along with the wind.

Harvard College Observatory, Cambridge, Jan. 1.

The Great Lake Basins of the St. Lawrence.

THE following are the conclusions of a paper under the above title to appear during January in the *Canadian Record of Science*, and the object of which is to suggest what has been the origin of the present contours of the Great Lakes:—

That glaciers, while contributing some results, had not much effect in eroding the lake-basins proper, or in shaping the present general outlines.

That the superficial deposits are the accumulations of denudation during immense periods of time since the carboniferous and earlier eras, and are not to be specially credited to the operation of glaciers.

That Lake Superior is the most ancient of the lakes, dating its origin as far back as Cambrian, Keweenawan, and Huronian times; that it is, in part at least, a synclinal trough; that volcanic action has had most to do with its origin and the shaping of its coasts; that its early outlet was through the depression in Whitefish Bay; and that its waters joined the great pre-glacial river system at or near the Straits of Mackinac.

That Lakes Michigan, Huron, and Ontario were originally the bed of a pre-glacial river which first crossed the Ontario peninsula along the Niagara escarpment, and afterwards was diverted to a course by way of Long Point, Lake Erie, and the Dundas valley; that their basins were largely defined by the elevation of the Niagara and Hudson River escarpments, and in more recent times by warping of the strata and deposit of superficial sands and clays which blocked the old river-channels and resulted in the lake-basins retaining their water on the final elevation of the land to its present general levels.

That the pre-glacial river system expanded into lakes of some size in each of the present basins of Lakes Michigan, Huron, Erie, and Ontario.

That Lakes Erie and St. Clair are the most recent of the lakes, and have at one time been more closely united; and that the formation of this united lake was due to the blocking of the old outlets both by superficial deposits and warping of the strata, and to the water being thus retained in the basin on the final elevation of the land to the levels of to-day.

That great fractures at or near the outcrops of the strata occasioned by the directions of the forces which elevated the strata, originated, in many instances, the deep bays and inlets which indent the Niagara and Hudson River escarpments, and rocky coastlines of Lakes Michigan and Huron; these effects being afterwards supplemented by the action of waves, currents, atmospheric causes, and probably local glaciers.

That since the elevation of the land to the levels of to-day, the action of waves and currents on the clay cliffs and sand deposits has in many places greatly rounded off the general outlines of the coast, and the material from this and other sources has been spread over the lakes, or has served to create new features in the coastline elsewhere.

Montreal, December, 1888.

Color of Katy-did.

THERE has recently come into the possession of the writer a specimen of the Katy-did showing a remarkable variation in color. The whole body is of a beautiful and delicate rose-pink. The specimen, when captured, did not seem to be abnormal in any other respect. It has been identified by a member of the entomological division of the Agricultural Department as *Phylloptera oblongifolia*. It seems to be a rare variation, though from the same gentleman we learn that at least one similar case has been recorded. A specimen exactly like this one in color is mentioned by Riley in his "Sixth Report on the Insects of Missouri" as having been sent to him many years ago.

Evanson, Ill., Dec. 30.

Various Definitions of Manual Training.

AN article in *Science* of Jan. 4, under the caption of "An Authoritative Definition of Manual Training," embodies an abstract of the report of the special committee on manual training of the New Jersey Council of Education, the semi-annual meeting of which body was recently held at Trenton, N.J. The committee, in concluding its report, submitted the following resolution, which was unanimously adopted:—

Whereas there are several and conflicting uses of the term "manual training," be it hereby

Resolved that the New Jersey Council of Education defines "manual training" as "training in thought-expression by other means than gesture and verbal language, in such a carefully graded course of study as shall also provide adequate training for the judgment and the executive faculty." This training will necessarily include drawing and constructive work, but experience alone can determine by what special means this instruction may best be given.

From an educational standpoint, the definition of "manual training" formulated by the committee would appear to be indisputable; but that the definition, supported as it is by the broad pedagogic principles which underlie it, will be universally accepted as authoritative and final, is not as certain as that the definition is such as to best subserve true educational aims. At least, it is safe to say that thousands of educators and school-officers must eliminate from their minds the impression that manual training has for its object the learning of a trade or the acquisition of mechanical skill alone, ere the definition given by the committee can have free course.

Again: there are others who are unwilling to accept the *dicta* of schoolmen, and who insist upon the mere technical or industrial phase of manual training, and can see nothing beyond it. Any thing that does not centre in this is, to them, an indubitable evidence of inutility. Training of thought, of judgment, of expression, etc., as educational stimuli, do not as potent factors enter into their conception of the aim and end of manual training.

That the training of the school workshop has a reflex influence upon the traditional occupations and "studies" of the classroom, causing pupils to reflect, to compare, to be careful and exact in these also, has not thus far been taken into the estimate of the worth of manual training as generally as the facts warrant; for manual training is not that of the hand alone, but of the intellect as well.

The joint training of the mental faculties and the hands tends to dignify the labor of the latter,—the form of labor which by many is alone recognized as "work." But it does not end there: it affords at the same time opportunities for the discovery of latent inventive or mechanical genius, and, when such discovery is made, serves as a guide in the choice of employment.

One must necessarily lead an unsatisfactory and precarious existence, who, from a false estimate of the relative respectability of two or more employments, chooses that for which he has but little natural aptitude and less acquired skill. And is it not true that the popular education of the past has tended toward the making of such choices? Has it not tacitly inculcated the idea that professional employment—the law, medicine, the pulpit, or the professor's chair—is the "chief end of man" according to the creed of the schools? In numberless instances such choices have been made, with the attendant and natural result of dismal failure.

As a corrective, manual training brings to bear a species of craniology which will eventually develop a more rational creed; and this view of manual training I conceive to be entirely compatible with the definition which the committee on manual training formulated.

Paterson, N.J., Jan. 7.

Color-Blindness.

A SHORT time ago I tested the color-perception of forty-two boys who had had kindergarten training. Their ages were from nine to fifteen. Not one of them made an error in matching colors. They were not asked to name them. This result suggests further investigation upon this class of pupils, not only to add one more fact to our knowledge of color-blindness, but also to determine the value of early instruction in colors.

DELAY IS DANGEROUS.

We call attention to the new form of Accident (indemnity) Insurance policies, which are written by the Merchants' Casualty Insurance Association, 27 Park Row, New York City. John S. Purdy, Secretary. These policies cover weekly allowances of from \$10 to \$25, according to occupation, at a cost of only \$6 a year exclusive of the cost to join, which is \$5 payable once only. The public, as a rule, carry life insurance, and the ordinary accident policies issued by companies, paying a sum in case of death, is not so desirable as one of these indemnity policies in case of accidents, which are so plentiful in this fast age with its railroad horrors, fast driving, electric wires and other countless forms of danger to which the public is constantly exposed. The fact of the Association having no unpaid claims, and its having just passed an examination by the Insurance Department of New York State, shows that the management is liberal with its policy-holders and conservative in its action. The Association also desires to secure energetic Agents in every village and town, to whom territory and favorable terms will be given.

THE AMERICAN COMMONWEALTH

BY

JAMES BRYCE, M.P., D.C.L.,

Author of "The Holy Roman Empire."

SELECTED PRESS NOTICES.

"A work unique in scope, spirit, and knowledge. There is nothing like it anywhere, extant,—nothing that approaches it. . . . Every thoughtful American will read it."—*New York Times*.

"We have here a storehouse of political information regarding America such as no other writer, American or other, has ever provided in one work."—*New York Tribune*.

"We have no hesitation in placing this book at the head of those which pretend to treat of our form of government in theory and in its practical working."—*N. Y. Evening Post*.

"One must look far and wide, through dozens of volumes, for anything like the information and the intelligent criticism which are here to be found."—*Boston Herald*.

"With very much more than the ordinary emphasis must it be said that 'The American Commonwealth' deserves a very careful reading among the 60,000,000 of Americans whom it concerns."—*Morning Journal*.

"The event of the year in the literary world takes place to-day in the publication by Messrs. Macmillan of Mr. Bryce's monumental work on 'The American Commonwealth.'"—*Fall Mall Gazette*.

"Prof. Bryce himself is so well known in literature and in public life that any book from him is sure to be seriously discussed. Especially is this true of an elaborate work on American institutions."—*G. W. S., in New York Tribune*.

"This splendid work on the institutions of the United States will prove the great work of the year for all thoughtful readers in this country."—*Washington Capital*.

Insurance.

DELAY IS DANGEROUS.

We call attention to the new form of Accident (indemnity) Insurance policies, which are written by the Merchant's Casualty Insurance Association, 21 Park Row, New York City, John S. Purdy, Secretary. These policies cover weekly allowances of from \$10 to \$25, according to occupation, at a cost of only \$6 a year exclusive of the cost to join, which is \$5 payable once only. The public, as a rule, carry life insurance, and the ordinary accident policies issued by companies, paying a sum in case of death, is not so desirable as one of these indemnity policies in case of accidents, which are so plentiful in this fast age with its railroad horrors, fast driving, electric wires and other countless forms of danger to which the public is constantly exposed. The fact of the Association having no unpaid claims, and its having just passed an examination by the Insurance Department of New York State, shows that the management is liberal with its policy-holders and conservative in its action. The Association also desires to secure energetic Agents in every village and town, to whom territory and favorable terms will be given.

GUARANTY INVESTMENT COMPANY

CAPITAL \$250,000.

Offices: Atchison, Kan. 191 Broadway, New York. 222 Walnut St., Phila.

Hon. ALBERT H. HORTON (Chief Justice, Kansas Supreme Court), Topeka, Kan., Pres't.

7% Guaranteed Farm Mortgages 7%

The Guarantee Investment Company makes loans upon fertile farms in the choicest portions of Kansas and Nebraska and has adopted the policy of sending a Committee of its Investors each year to examine its loans and methods of business.

The Committee this year consisted of PROF. A. H. BERLIN, Principal of the High School Montrose, Pa., and MAJ. THEODORE L. POOLE, Ex-U. S. Pension Agent, Syracuse, N. Y. Both of these gentlemen are persons of the highest character and have the confidence of the Communities in which they reside.

The Committee has recently returned and has made a very interesting Report upon the general development of Kansas and Nebraska as well as the business of the Company. The Company will be glad to send this Report to any address.

The following names are taken from the long list of Investors in our Mortgages:

(See if Some Friend of Yours is not in the List.)

ELECTRIC LIGHTING.—A MODEL CENTRAL STATION.

EXPERIENCE has shown that to attain the best commercial results in electric lighting, the final expression of which comes out in

station, the reduced plan and elevations herewith, of a simple and efficient station, will be found of interest. The station is that of the East End Electric Light Company, at East Liberty, Penn., operating the Westinghouse alternate-current system of distribution. The service from this station covers a very extended area, comprising the business portion of the city, which lies within an average distance of half a mile from the station, ramifying through an extended series of residence streets of the better class, and carrying

WESTINGHOUSE ELECTRIC-LIGHT STATION AT EAST LIBERTY, PENN.

END-ELEVATION.

PLAN AND SIDE-ELEVATION OF WESTINGHOUSE ELECTRIC-LIGHT STATION AT EAST LIBERTY, PENN.

dividends, too much care and knowledge cannot be brought to bear upon the steam and electrical engineering involved in the construction of the plant, from the foundations of the building, to the lamp wired on the premises of the consumer. The conditions, however, are found so varied in different localities that it is manifestly impossible to establish any fixed rules. As an illustration, however, which seems to contain the essential ideas of a well-considered

one special line out as far as the distant suburb of Swissvale, the last lamp being at a distance of four miles and a quarter from the dynamo.

The arrangement of the station is clearly indicated. It is a substantial but inexpensive one-story building of brick, containing the offices of the company and the storeroom for material, in addition to the dynamo and boiler room. The plant at present has an ag-

gregate capacity of about 8,000 lamps. Dynamos and engines are on the same floor, every part of which is constantly under the eye of a single attendant. Both engines and dynamos stand on brick foundations, the floor itself being of cement. Each engine is belted direct to its dynamo, no power being wasted in transmission; and the subdivision of power enables the wide fluctuations of load to be met by stopping and starting any engine and dynamo as needed, thus operating the whole station under the highest possible economical conditions at any moment. The steam-pipe is brought along the engine-room overhead, and the engines exhaust into a main laid in a covered trench underneath the floor, every part being accessible. All drips and overflows are run into a sewer. Two exciting dynamos are provided, as shown on the left of the dynamo-room, each adequate to supply current to the fields of all the alternating dynamos of the station, and each driven independently by its own engine. But one engine and exciter is therefore run at any time, the other standing ready as a relay in emergency. Moreover, the position of the engines and exciters is such that by changing a belt either engine can drive either exciter, and thus the chance of possible stoppage is reduced fourfold. The Westinghouse Company regard this latter arrangement as representing the best possible engineering, and strongly urge it upon every station of any considerable magnitude. Two overhead travelling-cranes traverse the whole length of the building over the engines and dynamos.

In a station so arranged, the labor is reduced to a minimum. With natural gas, of course, but one fireman is required; firing with coal, two firemen will be on duty in the first run of the evening, and one in the second run. But one attendant is required in the dynamo-room at any time, the lightness of his duties permitting him to give all necessary attention to the engines, dynamos, exciters, and switch-board. It is obvious that this general plan can be advantageously followed in most instances.

COAL-MINING MACHINES OPERATED BY ELECTRICITY.

THERE has probably been no greater advance in the mining-field effected during the past decade than the general introduction of electricity for power and lighting purposes.

The advantage of using electricity, its simplicity, compactness, safety, cleanliness, and reliability over the use of steam for power, were early recognized by mining engineers, and electricity is now generally regarded as the most convenient agent at the miner's disposal for transmitting his power into the interior of the mine.

One of the newest and latest applications of electric power to mining-work can be seen daily in operation at Mr. T. C. Heimes's "Drane Colliery," near Osceola, Clearfield County, Penn. Here a most interesting application of motors for mining-work has been devised by Mr. F. M. Lechner for operating a coal-cutter by electricity.

Mr. Lechner is well known as being not only the first inventor of coal-cutting machinery, but also the first to operate compressed air in mines for this purpose. His long practice and experience in the coal-mining field have made him familiar with all the difficulties attending the use of machinery in mining-work, and, ever since electric power has been in use for industrial purposes, he has made a study of the problems in adapting electric power to this work.

It soon became evident to Mr. Lechner that the best results could only be obtained by operating the motor and cutter apart, as otherwise the size and weight of the cutter with the motor mounted upon it would prevent its easy transportation in the mine.

In order to do this, the following arrangement has been adopted in the mine before mentioned, and has proved very successful. The motor, which is a 10 horse-power of the Sprague type, is mounted upon a truck running upon rails, so that it can be very easily handled and hauled from one position to another, as occasion requires. The entire weight of the motor is less than 1,000 pounds.

The cutter operated by the motor, which in this case is the "New Lechner," is set in position in the room to be cleared, and is connected with the motor by a five-eighths inch rope belt, running in V-shaped grooved sheaves, one being on the motor, and the other on the cutter.

This connection is long enough to allow the motor to be operated 30 feet away from the cutter, and the motor has been set in a position in this mine 1,600 feet away from the dynamo. The motor is held in position by guys at the point of use.

By means of screw-jacks that can be easily adjusted to any height, with loose sheaves upon them, the cutter can be operated at any angle from the motor; and the connection is made taut by moving the truck upon which the motor rests, and securing it in the right position by guys.

All mining engineers are familiar with the difficulty attending the working of the cutters in the limited space generally allotted them in mines, and know how essential it is to have every machine divested of every pound of surplus weight. They also know what care must be exercised in moving it with great iron crowbars, to prevent injury to the more delicate parts of the engines; and, however careful, how frequent it is that connecting rods and other parts are so impaired that the machine has to be sent to the shop; then how the rugged action of the engines shakes every thing loose on the machine, however firmly they may appear to be adjusted. All this is removed by the absence of the engines, the machine running as smoothly as a buzz-saw, and, as a consequence, cutting with the same facility. By this plan, three machines can be operated by one motor; for, when one room is cut, the motor can at once be hauled to another room, where a machine is in readiness and position, cut that room, and pass to a third while the coal is being removed from the first two, and the cutters being again placed in position.

It was found, upon a preliminary trial of this apparatus at the Osceola Mines, that by its use two men are able to excavate 100 tons in 10 hours, and that they can move the cutter as often as desired without any auxiliary aid.

The efficiency of both dynamo and motor is over 90 per cent; so that, allowing 10 per cent drop on the line, nearly 73 per cent of the power delivered to the dynamo-pulley can be depended upon at the motor for work.

It has been estimated that the cost of equipping a mine for the purpose of operating machinery with electricity is only about one-half the cost of equipping it with compressed air, and the price of maintenance shows about the same proportion of saving.

HEALTH MATTERS.

The Germ Theory in Consumption.

"WHAT Changes has the Acceptance of the Germ Theory made in Measures for the Prevention and Treatment of Consumption?" is the title of an essay by Dr. Charles V. Chapin of Providence, to whom was awarded a premium of two hundred dollars by the trustees of the Fisk Fund. In this essay Dr. Chapin has given an admirable *résumé* of all that has been written about consumption from the time of Hippocrates to the present day. After a careful examination of the literature of the subject, he thinks that we are justified in the conclusion that the acceptance of the germ theory has made no direct or important addition either to the hygiene or medicinal treatment of consumption. He thinks, however, that it should have great influence. It tells us plainly what we ought to do. We simply do not obey its behests. The germ theory—now no longer a theory in the case of tubercular consumption—tells us that we have to do with a contagious disease. Now, there is no theoretical reason why a purely contagious disease like tuberculosis cannot be exterminated. If we can prevent the spread of contagion at all, we can prevent it entirely. The enormous value of preventive measures, isolation, disinfection, and quarantine, is well illustrated in the history of cholera, typhus-fever, and yellow-fever in the United States. By keeping out the virus of these diseases, or destroying it when it had gained access to our shores, we have for a number of years been remarkably free from these diseases, and it is certain that if these precautions had not been taken we should have suffered severely. For obvious reasons the suppression of tuberculosis is not so easy a matter as the suppression of cholera or yellow-fever. Neither is the suppression of scarlet-fever or small-pox as easy. Yet wherever the public have been educated to a correct appreciation of the contagious nature of scarlet-fever, the number of cases has diminished very much. Even in small-pox, with its virulent contagion, it is possible, by means of isolation and

disinfection, to check its spread even among an unvaccinated population, as has been illustrated many times of late in the anti-vaccination city of Leicester, England. We must now put tuberculosis among these diseases, and, though its theoretical suppression is simple, its actual extermination is a very difficult problem. It lies largely with the medical profession how long tubercular disease shall decimate the human race. The physicians are the educators of the people in these matters. When the doctor shall teach that tuberculosis is contagious, the people will believe, and will govern themselves accordingly. In combating contagious diseases the preventive measures taken often give discouraging results. This will be particularly so in tubercular disease. Halfway measures secure less than halfway results, and these alienate the support of those who only indifferently believe in contagion and the importance of precautionary measures. Efficient means of suppression are radical, and bear hard on the individual: they are not complied with, and they produce violent opposition. Yet, difficult as it may be, the medical profession should take aggressive action against this disease. We have no right to wait for the discovery of a specific, or the gradual evolution of a phthisis-proof race. We must take the world as we find it, full of men and women predisposed to tubercular phthisis, and with no idea of its contagious nature. What can we do about it?

1. Teach the people the true nature of tuberculosis; that no one ever has tubercular consumption unless the tubercle bacilli find their way into the lungs.

2. Teach them also, that, even if it finds its way there, it will not grow unless the conditions are right. Teach fathers and mothers how to rear healthy boys and girls. Tell them what to eat and what to wear, to exercise, to breath fresh air. This alone would exterminate phthisis.

3. The contagion must be destroyed. Fortunately in this disease there is no need of isolation. Disinfection is enough. The consumptive patient gives off the poison only in the sputum, or perchance the other excreta, if the disease extend beyond the lungs. The virus is not given off from these while moist. We must therefore disinfect all sputum at once with mercuric bi-chloride. Cloths must be used instead of handkerchiefs, and then burned; or, if the latter are used, they should be often changed, and immediately put in a bi-chloride solution and boiled. Bed-linen should be treated in the same way. Frequent disinfection of the entire person, and fumigation of the apartment, would be safe additions to the preventive measures.

4. Persons who have a marked predisposition to the disease had best not come in close contact with the phthisical. Children should never have tubercular nurses, wet or dry. In the case of consumptives very great attention should be paid to ventilation, and to the alimentation both of the patient and the attendants.

Such measures, if rigidly carried out, would be of enormous service in preventing this disease. But with the increasing prevalence of tuberculosis among domestic animals, something more is imperatively demanded. Active measures should be taken to free the country from animal tuberculosis. The proper authority for dealing with this, as with all other contagious diseases of animals, is the Bureau of Animal Industry of the Department of Agriculture. It is a wasteful method for States to act independently. The powers and expenditure of this bureau should be greatly increased, and it should take active measures against this disease. The exact measures suggested are, —

1. The reporting of all cases of tuberculosis in domestic animals to the proper authority, by both owners and veterinaries, or other persons having a knowledge of the same.

2. The slaughter of all infected animals, and the isolation and slaughter of all exposed to infection. The government should partially indemnify all owners of slaughtered cattle.

3. Thorough disinfection of all buildings occupied by diseased cattle.

4. The confiscation of the flesh and milk and milk products of all tuberculous animals.

Pasteur's Method.

"Pasteur's method hardly attracts any attention now, and seems to be in a fair way to die a natural death." Such is a statement

made by Dr. Charles W. Dulles, in his report on hydrophobia to the Medical Society of the State of Pennsylvania. In support of this statement, he quotes from a report of Dr. Dujardin-Beaumez to the effect that there were nine deaths from hydrophobia in Paris during 1887, which was more than in 1880, 1883, 1884, or 1886. Five of these deaths were of persons less than fifteen years old. In one of the cases the patient was not bitten at all, but was simply licked on an abraded spot. Eight of the patients were bitten by dogs, and one by a cat. Two of the nine patients had been treated by Pasteur; and their death is explained by Dujardin-Beaumez on the ground that his method was not thoroughly carried out. The total number of persons treated by Pasteur was only 306 persons from Paris, bitten by dogs supposed to be rabid, as against about 300 a month one year ago.

These facts, Dr. Dulles thinks, show two very important things. One is, that the application of Pasteur's method has had no effect in reducing the usual mortality from so-called hydrophobia in Paris, which confirms the opinion in regard to its merits which he has repeatedly expressed; the other is, that, in spite of the artificial stimulus furnished by the French reception of Pasteur's method, the number of those who fall into the terror of hydrophobia is diminishing in France, and this leads to the hope that before long France will compare favorably with Germany and America, which have refused to be carried away by the false notions in regard to hydrophobia put forward by one who knows nothing about it but what he has manufactured in his laboratory.

There is a great significance in the fact that disbelief in the theories of Pasteur, which some of his partisans have stigmatized as harsh or unscientific, has been found to go with a singular immunity from the ravages of so-called hydrophobia. This holds true to such an extent that one may safely say that the degree of acceptance of Pasteur's theories in any country will furnish a measure of the number of cases and deaths from hydrophobia. In Germany these theories have never obtained a foothold, and hydrophobia is almost unknown: in America the attempt to import them ended in speedy failure, and here hydrophobia is almost equally unknown.

A detailed account of fifteen fatal cases of hydrophobia is given by the author of the paper. Attention is called by him to the following points, which are brought out in a study of these cases: —

1. *The Effect of Anticipation of Hydrophobia.* — This is said to have been present in seven of the fifteen cases, and may be suspected in more.

2. *The Lack of Evidence of Rabies in the Animal which did the Biting.* — Not one of the animals furnished more than ground for a suspicion that it was rabid. The fact that a fighting dog bites a man who interferes with it, is no evidence that it is rabid, nor is the manifestation of a vicious temper a good evidence of rabies. The same may be said of death in a fit.

3. *The Effect of a Diagnosis of Hydrophobia.* — In ten of the fifteen cases it is stated that the physicians made an early diagnosis of hydrophobia, and presumably they failed to conceal the fact from the patient.

4. *The Effect of applying the Test of the Water.* — This is said to have been done in seven of the fifteen cases, and it was probably done in almost all of them.

5. *The Assertion that Canine Symptoms were Present.* — Five of the patients are said to have whined, or howled, or snapped, or bitten at their attendants.

6. *The Frequency of Forcible Restraint.* — This is said to have been employed in eight of the cases.

7. *The Uselessness of administering Narcotics.* — Powerful narcotics are said to have been used in ten of the cases, and they were probably used in all. Curare is said to have been used in four cases.

In concluding his report, Dr. Dulles says, "I have on several previous occasions declared my belief that hydrophobia is not a specific inoculable disease. I believe this more firmly to-day than ever before. I do not deny that men and women and children sometimes fall into a peculiar state after a dog-bite, and die in due time; but I do deny that this is attributable to any specific virus in the dog's saliva. The same thing has occurred too often from other causes to justify one in charging it to a specific virus when it

allows a dog-bite. And I believe that the rejection of the specific theory will do more to banish hydrophobia from the world than any thing which we have ever heard of.

"The word 'hydrophobia' should be used only to describe a condition, and not a disease, as we use the word 'convulsions;' and it should be remembered that this condition may be present in a great number of diseases, as I tried to show you when you last met in this city, in 1884.

"I firmly and honestly believe, that, if this view of what is called hydrophobia were generally accepted, the disorder would shrink and disappear, as the geni said, in the tales of the 'Arabian Nights,' to have shrunk and disappeared when the right word was spoken; and I call your attention to the fact that hydrophobia is now almost unknown in our own State of Pennsylvania. Not a single case has occurred in our State since we last met, and I cannot but attribute this fact partly to the extent to which your judgment confirms the opinions to which my studies of hydrophobia have led me.

"I do not despair of seeing the belief in hydrophobia follow the belief in witchcraft, which once had the support of Church and State, of the medical profession and the laity, but which now, thank God! torments our fellow-men no more. So long, at least, as Pennsylvania presents the spectacle of freedom from the thraldom of ancient superstitions in regard to hydrophobia, and freedom from its curse, I cannot but think that the former has some causal connection with the latter."

INEBRIATE ASYLUMS.—Dr. T. D. Crothers of Hartford, Conn., in an address on "Inebriate Asylums and their Work," delivered at Toronto, Can., draws the following conclusions as being supported by the latest teachings of science and experience: 1. Inebriate hospitals must take the place of jails and station-houses. Such places are dangerous in their mental and physical surroundings, by intensifying the degeneration, and removing the patient beyond hope of recovery. They are in many cases literal training-stations for mustering in armies of chronic maniacs that never desert or leave the ranks until crushed out forever. 2. Inebriate hospitals should receive the incurable inebriates, and make them self-supporting, and build them up physically and mentally. They would relieve the tax-payer, and relieve society of untold burdens of sorrow and misery. 3. Inebriate hospitals should receive the recent cases, and place them in the highest conditions of enforced health and vigor, and thus return a large number to health and sobriety again. 4. Inebriate hospitals can and should be self-supporting when once established. They should be managed on scientific business principles, like military training-schools. 5. Inebriate hospitals should be built from the money raised by taxes on the sale of spirits, on the principle that every business should be obliged to provide for the accidents which grow out of it. 6. These are the realities which every inebriate hospital is approaching, and which all experience points out as practical and literal in the near future. 7. The inebriate hospitals of to-day are only in the infancy of their work, contending with great opposition and prejudice, misunderstood, condemned, and working against innumerable obstacles. 8. The work of the present inebriate hospitals, notwithstanding all the difficulties and imperfections, has the grandest promise for the future, and encouragement for further effort in this field, along the line of scientific research. 9. Lastly, there is an intense personality in inebriate hospitals to each one of us. They may bring salvation and restoration to some one near and dear. They may be fountains of healing whose influence shall cross and influence our pathway in many ways. 10. Inebriate hospitals and their work is the great new land which only a few settlers have reached. They are calling to us to come up and occupy, and thus help the race on in the great march from the lower to the higher.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

THROUGH the efforts of Mr. George F. Porter, of the transportation committee, one and one-third rates were obtained some time ago for all delegates travelling to the coming convention in Chicago, in the territory of the Trunk Line Association. It gives us pleasure to now announce that the same active worker has secured the same

rates from the Central Traffic Association, whose territory covers all that portion of the United States lying west of Pittsburgh (Penn.), Buffalo (N.Y.), and Bellaire (O.), and north of the Ohio River and east of Chicago (Ill.). The method of obtaining the return ticket from the Chicago Convention (Feb. 19, 20, and 21) is extremely simple.

First, Each person must purchase (not more than three days prior to the date of the meeting nor later than three days after the commencement of the meeting) a first-class ticket (either unlimited or limited) to the place of meeting, for which he will pay the regular tariff fare, and upon request the ticket-agent will issue to him a certificate of such purchase properly filled up and signed by said ticket-agent. Second, If through tickets cannot be procured at the starting-point, the person will purchase to the nearest point where such through tickets can be obtained, and there repurchase through to place of meeting, requesting a certificate properly filled out by the agent at the point where repurchase is made. Third, Tickets for the return journey will be sold by the ticket-agents at the place of meeting at one-third the highest limited fare, only to those holding certificates signed by the ticket-agent at point where through ticket to the place of meeting was purchased, and countersigned by the secretary or clerk of the convention, certifying that the holder has been in attendance upon the convention. Fourth, It is absolutely necessary that a certificate be procured, as it indicates that full fare has been paid for the going journey, and that the person is therefore entitled to the excursion fare returning. It will also determine the route *via* which the ticket for return journey should be sold; and *without it no reduction will be made*, as the rule of the association is that "no refund of fare will be made on any account whatever, because of the failure of the parties to obtain certificates." Fifth, Tickets for return journey will be furnished only on certificates procured not more than *three days* before the meeting assembles, nor later than three days after the commencement of the meeting, and will be available for continuous passage only; no stop-over privileges being allowed on tickets sold at less than full fares. Certificates will not be honored unless presented within *three days* after the date of the adjournment of the convention. Sixth, Ticket-agents will be instructed that excursion fares will not be available unless the holders of certificates are properly identified, as above described, by the secretary, on the certificate, which identification includes the statement that one hundred or more persons, who have purchased full-fare tickets for the going passage, and hold properly receipted certificates, have been in attendance at the meeting. The certificates are not transferable, and the signature affixed at the starting-point, compared with the signature to the receipt, will enable the ticket-agent to detect any attempted transfer. This convention will undoubtedly be the largest and most interesting which has ever been held, and will be accompanied by an exhibition of electric light and power apparatus and supplies, which will be in a large hall devoted entirely to this purpose.

Electric light and power men who are not now members of the association would do well to join at once, which they can do by addressing the secretary, Allan V. Garratt, at 16 East 23d Street New York City.

So large a number of the representative manufacturers and dealers in the electric light and power apparatus and supplies have expressed a wish that facilities be afforded them to make a very large exhibit at the coming convention of the National Electric Light Association in Chicago, in February, that the executive committee has decided to secure a large hall, where ample room for each exhibitor may be had. Before the committee can proceed further with the matter, it will be necessary to know how many exhibitors there will be, how many square feet of floor space each will want, how many horse-power in steam, how many horse-power from shafting, and how much current and at what electro-motive force. For the purpose of the committee at present, it will only be necessary to have an approximate idea of what is wanted: therefore any intending exhibitors should apply at once to Mr. B. E. Sunny, chairman executive committee, 148 Michigan Avenue, Chicago, Ill.

GINN & CO. announce that the new edition of Lanman's "Sanskrit Reader" is ready.

THE AGASSIZ ASSOCIATION.¹

THE Agassiz Association, as most of you know, is a union of local societies which have been organized for the study of nature by personal observation.

It is not for the sake of any money you may make out of it that we advocate the study of nature. If it were, our association must change its name; for Louis Agassiz used to say that he had "no time to make money." We urge you to join us in this study for the sake of learning what is true. We honor those who set knowledge above "gold and the crystal," and esteem the price of wisdom "above rubies." There is great pleasure in the mere seeking of truth. There is a delight in all discovery.

Now, nature offers to every one of us new gifts every day. No matter how long a beetle may have been known to others, until you have found it for yourself, it is not old to you. So, too, although the species may be familiar, each new specimen has the charm of novelty.

But besides the pleasure of learning, it has been found that one who studies nature aright greatly improves his powers of attention, discrimination, and reasoning. The right way to study nature is to use your own eyes instead of depending upon printed accounts of what somebody else has seen with his. It is a lazy boy who hires another to do his fishing for him. To depend upon the observation of others will no more increase your mental powers than it would improve your muscular development if a friend should swing Indian clubs for you. To one who tries to get all his knowledge of nature from books, every thing comes at second-hand: nothing comes to him as his own discovery. There is no joy in it, and but little benefit. That is why the Agassiz Association always insists upon "personal observation," which is simply a Latinized way of saying, "using your own eyes to see what you can see."

This statement should make plain the nature of the work expected from the little clubs we are organizing in so many cities and towns. The members are to search and find out what there is of interest within, say, five miles of home.

In order to do this, they will make excursions after flowers, minerals, insects, or whatever they most care about, and perhaps make a map showing just where each sort may be found. Of course, they will find a few books useful to help them learn the names of what they find; they will need a cabinet in which to keep their treasures; and they will be glad to have wise men lecture to them now and then, and explain the things that are too hard to study out for themselves. I cannot see that it would do any great harm even if every town and village in the land should have its natural science club, with a little library and museum, and with wide-awake members ready at any time to give the curious traveller an account of all the interesting objects to be found in an afternoon's walk, and able to show him specimens of each variety, nicely preserved, accurately classified, and neatly labelled. All who have read "St. Nicholas" carefully for a few years past, know that the Agassiz Association has organized societies of this sort very successfully, and that the boys and girls—yes, and their parents and teachers, too—have found much recreation in these clubs, and learned much natural history and natural science as well.

During this very year, and since I last wrote to you about our association, more than a hundred new clubs or "chapters" have been added to our roll; and that means more than a thousand new members. You see, there must be at least four in a chapter, and there may be as many more as are desired. One of our chapters, in New Brunswick, N.J., has more than four hundred members, with about a dozen professors to guide them, and there are microscopes, and stereopticons, and all sorts of instruments to aid them in their studies.

After a number of these little clubs are fairly at work in any large city, or throughout a State, they often wish to become better acquainted with one another, and so the clubs hold joint meetings occasionally, and they call these large united gatherings "assemblies."

These assemblies elect their own officers, and hold regular conventions. One of the largest has been formed this year by combining the various societies in Massachusetts. We had a very suc-

cessful convention in Boston on Decoration Day. This holiday happens to occur within a few days of Agassiz's birthday, which is very pleasant and convenient for us. There was an address from Professor Hyatt of the Boston Society of Natural History, a man deservedly popular with young people; and one from Professor Crosby, who has been conducting for our benefit a very interesting course of lessons in mineralogy, extending over more than a year (for which lessons he furnishes the specimens and necessary instruments). Professor Morse of Salem, the author of an excellent book on the study of zoology, also lectured to us. Professor Morse's son is a member of a very active chapter of the Agassiz Association, so active that it organized a stock company of boys and built a house for their meetings. Dr. Lincoln, who is now helping the members of our Boston Assembly to make a thorough study of all minerals to be found within ten miles of the Boston State House, was also one of our instructors.

Another of our recently formed assemblies is the State Assembly of New Jersey. Rev. L. H. Lighthouse is president of this assembly; and while I write (Aug. 10), he is conducting a well-attended seaside meeting. It is to continue for a week. Every morning the members make an excursion, under the lead of some expert, and may have the choice of botany, entomology, or microscopy. Every afternoon they gather in the large Educational Hall, and examine their "finds," with the assistance of the professor who led them in the morning. Every evening they attend a lecture, usually illustrated by the gas-microscope or by the stereopticon. Professor Austen, the president of the New Brunswick Chapter, has been very helpful in organizing and managing this pleasant seaside assembly.

The Iowa State Assembly is about to hold its fifth annual convention. Iowa conventions are always successful. All the chapters send delegates, who bring to the meeting not only carefully written reports of the work the chapters have done during the year, but also the finest of the specimens collected. The young men, and young women too, give most interesting accounts of their studies, illustrating them with specimens, original drawings, diagrams, and maps. Then there is a dinner, a meeting for the practical demonstration of their methods of work, and one or two excursions. This assembly offers three prizes each year for the best work done in any chapter since the previous convention.

I must not stop to give in detail accounts even of all our large assemblies; still less can I undertake to tell of the individual chapters. Among so many, it would be impossible to select single ones for special praise. Merely by way of illustration, however, I may mention Chapter No. 3, of Frankford, Philadelphia, which, under the lead of John Shallcross and Robert T. Taylor, has maintained itself in full vigor since the first year of our extension beyond Massachusetts, and which was instrumental in founding the Philadelphia Assembly, the first assembly in the association.

The Manhattan Chapter of New York City is a noteworthy illustration of what young people can do without aid. This society has grown from a handful of boys, meeting from house to house, into a club of a hundred young men, renting rooms at No. 103 Lexington Avenue, and exhibiting there a fine collection fairly representing the natural productions of Manhattan Island. This chapter, like all others, is glad to welcome visitors to its rooms.

The largest chapter in Massachusetts is No. 448, of Fitchburg, with a hundred and fifty members. This chapter has published a handsome pamphlet, giving an account of all the flowering plants to be found in the vicinity.

A new sort of club has been devised and put into successful operation during the year. Chapters of this sort are called "corresponding chapters." They are composed of members who do not live in the same town, but are united by their common interest in the same study. The first of these was the Archæological Chapter. Its President is Hilborne T. Cresson of Philadelphia; vice-president, Dr. C. C. Abbott of Trenton, N.J.; secretary, A. H. Leitch of Dayton, O. The members of this club are grown men; and they propose, under the auspices and general direction of the Peabody Museum of Cambridge, to preserve ancient mounds from the spade of the vandal and the speculator, until they can be properly and scientifically explored under competent supervision. Two other corresponding chapters recently added are the Gray Memorial

¹ From St. Nicholas for November, 1888.

Chapter, for the study of botany, and the Isaac Lea Memorial Chapter, for the study of shells.

It is worthy of mention that from the beginning the girls and women have kept equal step with the boys and men, not only in patient and thorough work in field and laboratory, but also in the work of organization and direction. Many ladies are efficient secretaries, curators, or presidents of chapters, and one girl has held with honor the office of president of a State assembly.

We have been asked why we favor the establishment of societies. Why should not the study be carried on by individuals? All true study, it is claimed by these critics, is prosecuted in solitude and silence. Great books are not written by a society of authors; poets do not sing in chorus; artists do not paint in clubs; and the light of scientific discovery has come to the world in little flashes of illumination, which have fallen singly upon the minds of silent and lonely thinkers.

There is much truth in this argument, and there can be no good work done either in or out of any society unless each separate worker acts and thinks for and by himself. Yet there are important advantages which are secured by united effort. Every one who finds any thing that interests him, wants some one to whom he can show it. A pleasure shared is a pleasure doubled. Thus, at the meetings of our clubs, each member has a friendly audience to listen to the results of his private study. Then, too, when several friends join in a society, they are often able to buy more expensive books and instruments than any could afford alone. A library may be had, a microscope bought, a lecturer secured, a room rented, a building erected. Think, too, of the pleasure of these social gatherings, often enlivened by music and song; think of the pleasant excursions, picnics, or field-meetings, and the occasional evening receptions.

Besides, when we bring several of these local clubs into fellowship with one another through correspondence, exchanges, or a convention now and then, the pleasures and benefits are greatly increased, and many things are done which no single chapter could do. Storms can be traced and their courses represented on maps; erratic boulders can be tracked to their ancient homes; the routes of travel of birds and insects can be followed for hundreds of miles, and facts of interest gathered in every department of science.

One of the most important features of the last year's work has been in this direction. Simple blanks have been sent to different chapters, with the request that they be filled out with records of local observation in particular branches. One boy has prepared a set of blanks on which different observers are writing accounts of all the dragon-flies they may see, telling the place where each specimen was found, its name, description, habits, etc.; and other members have prepared similar blanks for records of observations on birds and minerals. In this way distant parts of the country are brought into friendly acquaintance; and boys of Maine and boys of Florida, girls of California and girls of Massachusetts, become interested in learning one another's thoughts, and in giving one another information and assistance.

Perhaps a more definite idea of what our boys and girls find in their rambles may be gained from a list of a few of the topics upon which members have made original notes during the year. From hundreds may be named these: "Two Rare Fossils from Catskill," "Rose-Leaf Galls," "White Blackbirds," "Ivy-Blossoms," "Curious Trees," "Animals that do not Drink," "Do Salmon Eat Birds?" "Complementary Colors," "An Abnormal Cabbage-Leaf," "A Living Barometer," "Rainbow and Sun-Dogs," "Double Adder's-Tongue," "New Jersey Butterflies," "Eggs of the Crayfish," "Colorado Ants," "Floating Pollen," "A Double Stinger," "Frost Pictures," "An Experience with a Heron," "A White Weasel," "A Strange Mouse," "Girls in a Silver-Mine."

In closing this brief report, I wish, in behalf of the Agassiz Association, again to invite all who are in any way interested in the study of nature to join us, either by organizing societies in their own towns, or, if that be impossible, by joining as individuals. All are welcome, from the oldest to the youngest. We have a council of fifty scientists always ready to receive from our members questions about whatever may puzzle them, and these gentlemen are eager to give all the help they can. We are just about to begin a

course of simple observation-lessons in botany, open to all our members. The plan is to send to every one who takes the course a set of perhaps fifty specimens, nicely prepared, with printed instructions on the proper way of so observing them as to see all that can be seen, and for telling in the proper way all that is seen — and nothing more. To all who would like to consider the question of joining the association, we will send, free, papers giving full directions for organizing a club or a chapter, or for joining alone. We will also send, until the supply is exhausted, an excellent wood-engraving of Agassiz, representing him examining a sea-urchin. This picture is printed on one of the papers of information, but is one of the best likenesses of Professor Agassiz in existence. All who are interested may address The Agassiz Association, 50 South Street, Pittsfield, Mass.

HARLAN H. BALLARD.

NOTES AND NEWS.

A REGULAR meeting of the American Physiological Association was held in the rooms of Jefferson Medical College, Philadelphia, on Dec. 29, and at the University of Pennsylvania on Dec. 31. A number of interesting communications were read. Professor Reichert recounted experiments showing that the anterior columns of the spinal cord possessed no irritability of their own, or that the power of excitability was confined to the posterior sensory columns. He also showed that the rate of transmission of a nervous impulse differed under different conditions. Dr. J. W. Warren described some recent experiments showing that a sensory impulse, such as the explosion of a torpedo, re-enforced the knee-jerk, and drew the curve showing the variation of this re-enforcement with the interval between the sensation and the knee-jerk. Dr. Donaldson showed specimens from which it could be seen that the effect of a long electrical stimulation was to decrease the size of the nuclei of ganglion-cells, and that the amount of this shrinkage was roughly proportional to the duration of the stimulation. Professor Martin in one paper gave the determinations of the minimal and maximal temperatures consistent with life that the blood supplied to an isolated heart could undergo, and in another showed that the variation in the amount of carbonic acid given off by a normal frog and one kept in the dark was due to the optical and not the psychic differences of the two states, because a frog deprived of its cerebral hemispheres acts in this respect just like a normal frog. All of these papers led to interesting discussions; and the discussion of Dr. Reichert's paper induced Dr. S. Weir Mitchell to place at the disposal of the society two hundred dollars, to be devoted towards aiding research upon the rate of nervous transmission, especially in man. The society was hospitably entertained, and found much pleasure in visiting the laboratories of the Jefferson College and the University of Pennsylvania. The members of the society were invited to participate in the International Congress of Physiologists to be held in Basle in 1889.

— Professor F. Janssen, in a recent number of the "Revue Scientifique," describes his interesting and arduous expedition to the Mont Blanc, undertaken in October of this year, in order to study the influence of the atmosphere upon the solar spectrum. It has long been a disputed question whether the oxygen lines are due to the solar or terrestrial atmosphere. This question can be solved only by observations on elevated stations, where the influence of the atmosphere of the earth is very small. In order to make the results still more satisfactory, Mr. Janssen selected the month of October, when the amount of vapor present is small. The ascent was very difficult on account of the lateness of the season, snow having covered the slopes of the mountain and the glaciers. Notwithstanding his advanced years, Mr. Janssen persevered, and, with the aid of a number of experienced guides, reached the Grands-Mulets, where the observations were to be made. He was favored by exceptionally clear weather, and on Oct. 14 observed the solar spectrum. The lines and bands of vapor were absent, and the bands of oxygen decreased rapidly with increasing altitude of the sun. At noon they had entirely disappeared. The lines, on the other hand, were still visible, but had become very faint. From these observations it appears that oxygen does not exist in the atmosphere of the sun in such form as to produce the lines which it produces in the form in which it occurs in the earth's atmosphere

—The American Historical Association held its fifth annual session last week, a large number of members being present. The president, William T. Poole, in his opening address, treated principally of the ordinance of 1787 for the North-west Territory, and called attention to the great need of impartial biographies of Gen. George W. Clark, La Salle, Kenton, and Father Hennepin; Gen. James Grant Wilson gave an account of the evolution of the "Cyclopedia of American Biography;" Dr. A. G. Warner read a treatise on town and county government in the United States; Professor McLaughlin of the University of Michigan rendered tribute to the influence of Gen. Cass on the development of the North-west; Professor Knight of the Ohio State University treated of the history of higher education in that section; Professor Allen of the University of Wisconsin presented a paper on the position of the North-west in general history; and Major J. W. Powell presented a language-map for North America, which has been prepared by the Bureau of Ethnology. It represents in graphic form the results of the investigations of many persons who have been engaged on the work for the past fifteen years. He explained the methods adopted in correlating and classifying the aboriginal tongues, and the historical researches that had been prosecuted to determine the pristine homes of the various tribes. He finally gave a characterization of Indian languages. Other papers were read by W. C. Fisher of Cornell; C. N. Morris of Berkeley; G. Brown Goode, assistant secretary of the Smithsonian; F. A. Bancroft, librarian of the State Department; H. C. Lee of Philadelphia; W. W. Henry of Richmond; and Clarence W. Bowen of New York. Officers of the association for the coming year were elected as follows: president, Charles Kendall Adams of Cornell University; vice-president, John Jay of New York; second vice-president, William Wirt Henry of Virginia; secretary, Herbert B. Adams of Johns Hopkins University; treasurer, Clarence Winthrop Bowen of New York. An executive committee, in addition to the above-named officers, were elected as follows: Rutherford B. Hayes, George P. Fisher, and John W. Burgess.

—At a recent meeting of the Royal Meteorological Society, Rev. I. A. Preston gave an interesting summary of phenological observations for 1888. He said that vegetation was generally backward throughout the season. In the south-west of England and south of Ireland plants were earlier than usual, but not elsewhere. In February they were from one to four weeks later, and gradually gained ground till June. In the south of Ireland they were slightly in advance of the average in June and July; in the south-west of England they just reached the average in July, while in Guernsey they were a fortnight later. Fruits generally were a failure, — very few really ripened, — and, from want of sun, were deficient in flavor. Hay-making was unusually late (as much as five weeks). It began in July or August, and was not entirely finished till late in September. Much of it was spoiled or secured in bad condition. Straw was plentiful, and, though the corn was not an average crop, the fine October enabled farmers to secure a better one than could have been expected. Roots were often a failure, and potatoes were much diseased. Capt. D. Wilson Barker read a paper entitled "A Winter's Weather in Massowah," in which he gave the results of four-hourly observations from December, 1887, to February, 1888; the highest shade temperature being 95°, and the lowest 68°.

—The observation of the total eclipse of the sun of Jan. 1, which was visible over a belt stretching from California to Manitoba, was favored by clear weather, and it is probable that results of great value have been obtained. The principal work was done by the Harvard University party at the Lick Observatory, by astronomers at Norman, Professor Swift near Chico, the Chabot Observatory, and people at Cloverdale. Professor Louis Smith was stationed at Nelson, Cal., and telegraphed the following as the result of his observations of the eclipse: "As far as affording opportunity to search for intra-mercurial planets, it was a failure from clouds and haze. All four contacts were well made, the chronometer watch previously set to Lick Observatory time being used. Five very small colorless protuberances were seen, all having pointed apices. Near the point of one was another detached from the sun. Bailey's beads were seen at the second and third contacts, but entirely unlike those seen at Denver in 1878. No chromosphere was visible,

though looked for. Mercury, Venus, Vega, and Alpha Cygni were seen. The corona could not be drawn, but as seen through the telescopes it was not very extensive." At Brandon, Manitoba, observations were made. At 3.15 o'clock, central time, 90° longitude, the first contact was observed. At 3.15.34 the shadow had crept over one-half the disk; at 3.15.47, three-quarters; and the totality occurred at 3.16.09. At the quarter a deep-reddish color was observable at the edge of the sun's disk, projecting from beneath the dark body. Immediately after, a sort of halo was formed around the disk, it is difficult to say whether of a greenish or bluish color. It was red at the outer edge, with the color deepening. At 3.15.34 a vibratory motion was visible around the outside of the sun's disk. At the three-quarter obscurity, jets from the upper right and lower left sides and from the lower left horn of the crescent were visible. The corona was irregular, extending to the left and right, — on the left above and on the right below. The corona was observed and sketched very carefully. This sketch was exhibited to other observers, who recognized the irregular shape it assumed. Above and below, the depth was not nearly so great as to the right and left. To the right the illumination assumed an almost square or block appearance, whereas to the left it was narrowest and more elongated. To the observers' view, the inner corona was distinctly visible immediately after totality on the upper left side. This phenomenon grew fainter for 28 seconds, and then more visible, until immediately before the sun's re-appearance, when it was again distinctly visible. On the bottom right-side corner of the inner corona appeared a luminous gold ring, and it was very beautiful during totality. Another observer used his telescope, and secured corroborative evidence of the above. In fact, so well defined was the corona, that to close and careful observers there was no difficulty in agreement. No streamers or filaments were observed. The time of totality, according to one observer, was 56 seconds, and according to another 57. As the eclipse neared totality, the thermometer fell very perceptibly. In fact, it became intensely cold. The vibratory motion already spoken of was distinctly seen on the walls of St. Matthew's Church close by. Stars could be seen studying the deep blue of the heavens. The corona was small and of a pearly lustre. In two places only several long rays were seen. Fuller reports may be expected at an early date.

—In behalf of the American Association for the Study and Cure of Inebriety, the sum of one hundred dollars is offered by Dr. L. D. Mason, vice-president of the society, for the best original essay on "The Pathological Lesions of Chronic Alcoholism Capable of Microscopic Demonstration." The essay is to be accompanied by carefully prepared microscopic slides, which are to demonstrate clearly and satisfactorily the pathological conditions which the essay considers. Conclusions resulting from experiments on animals will be admissible. Accurate drawings or micro-photographs of the slides are desired. The object of the essay will be to demonstrate, first, are these pathological lesions due to chronic alcoholism? second, are these lesions peculiar or not to chronic alcoholism? The microscopic specimens should be accompanied by an authentic alcoholic history; and other complications, as syphilis, should be excluded. The successful author will be promptly notified of his success, and asked to read and demonstrate his essay personally or by proxy, at a regular or special meeting of the Medical Microscopical Society of Brooklyn. The essay will then be published in the ensuing number of "The Journal of Inebriety" (T. D. Crothers, Hartford, Conn.) as the prize essay, and then returned to the author for further publication, or such use as he may desire. The following gentlemen have consented to act as a committee: W. H. Bates, M.D., chairman, 175 Remsen Street, Brooklyn, N.Y.; John E. Weeks, M.D., 43 West 18th Street, New York; Richmond Lennox, M.D., 164 Montague Street, Brooklyn, N.Y.

—The fourth annual meeting of the Indiana Academy of Science was held from Dec. 25 to Dec. 27 at Indianapolis. On Wednesday night Professor J. P. D. John delivered the presidential address, on "Religion and the Law of Continuity." The programme provides for papers to be read in four sections, — zoölogy; botany; geology and geography; chemistry, physics, and mathematics. Among the papers announced, those on zoölogy outnumber those in any other section.

THE RESULTS of the explorations of the Hemenway South-western Archaeological Expedition in 1887-88, under the direction of Frank Hamilton Cushing, promise to be of the greatest importance to our knowledge of ancient America. The plan of the researches is so comprehensive that we may expect they will clear up the history of the natives of the South-west States and Territories and of northern Mexico,—their somatological character as well as the origin and development of their peculiar culture. Mr. S. Baxter, secretary of the expedition, has recently reviewed the most important results hitherto reached. It has been ascertained that the culture of this region was identical with that of Zuni. The inhabitants of these ancient cities practised an elaborate and thorough system of co-operative river and rain irrigation, and seem to have had a system of canal navigation. They had domesticated animals, notably the turkey, and probably also the rabbit and a variety of the *Auchenia*, or llama. Mr. Cushing has also found facts which lead him to conclude that an entirely indigenous metallurgic art existed; that the natives knew how to reduce ores by smelting, and how to fuse and braze with terra-cotta and cane blowpipes. These researches are of the greatest value, as they are founded on studies of a surviving branch of the peoples once living in these regions, the customs of which serve as a clew to the finds made in the ruined cities. The final results of the expedition will undoubtedly form the starting-point for investigations into the ancient civilization of America.

AN AMERICAN GEOLOGIC SOCIETY.

WITH the activity in geologic investigation during the last decade there has grown up among American geologists the feeling that their work should be more fully co-ordinated and unified, and that more frequent opportunities for personal intercourse should be secured. This feeling took definite shape in 1881, when, at the Cincinnati meeting of the American Association, definite movement was made toward the co-ordination of the Federal and State geologic surveys, and toward the organization of an American geologic society.

The efforts of the geologists in attendance at Cincinnati were not, however, seconded by their absent brethren so warmly as to warrant the founding of the proposed society. The plan has since been kept in mind by its promoters, and during the past summer a call was issued for a meeting of geologists interested in the proposal to form such a society, in Cleveland, on Aug. 14 last. This call was met by a hearty response, and the twoscore of geologists present effected a preliminary organization, adopted a provisional constitution, and appointed a committee to call a subsequent meeting and complete the organization. This committee consisted of Professor Alexander Winchell of the University of Michigan; Professor John J. Stevenson of the University of the City of New York; Professor Charles H. Hitchcock of Dartmouth; Professor John R. Proctor, State geologist of Kentucky; and Professor Edward Orton, State geologist of Ohio.

The meeting for final organization took place in Sage Hall of Cornell University, at Ithaca, on Dec. 27. The attendance was small, but included representatives of a considerable part of the country. Chairman Winchell of the committee on organization presided; a list of 102 geologists, engaged in either original investigation or teaching, who had subscribed to the constitution and paid the entrance-fee, was read; and the provisional constitution prepared at Cleveland was adopted, and the organization thereby rendered complete. The following officers were then elected: president, Professor James Hall, State geologist of New York; first vice-president, Professor James D. Dana, Yale College; second vice-president, Professor Alexander Winchell, University of Michigan; secretary, Professor John J. Stevenson, University of the City of New York; treasurer, Professor Henry S. Williams, Cornell University; executive council, the above-named officers, and the following fellows at large,—Hon. J. W. Powell (director United States Geological Survey), Professor J. S. Newberry (Columbia College), and Professor C. H. Hitchcock (Dartmouth College). Two committees were appointed as follows: committee on revision of provisional constitution, Professor Alexander Winchell, Professor Henry S. Williams, Professor C. H. Hitchcock, Professor J. J. Stevenson, and H. L. Fairchild of the University of Rochester; advisory committee on publications, Professor Joseph LeConte (University of California), Mr. W. J. McGee (United States Geological Survey), Professor N. H. Winchell (State geologist of Minnesota), Professor I. C. White (University of West Virginia), Professor William M. Davis (Harvard University).

According to the terms of the provisional constitution, original fellows of the society comprise working and teaching geologists, who, being members or fellows of the American Association, subscribe to the constitution and pay the entrance-fee before Jan. 1, 1889. In addition to the 102 original fellows thus constituted, sixteen candidates for fellowship were elected at the Cleveland meeting. The society thus starts out with a membership of 118, including nearly every eminent geologist of the United States, and little if any undesirable material, and with a fund (derived wholly from membership-fees) of nearly twelve hundred dollars in the treasury.

It was the prevailing belief at the meeting that the Geologic Society of America is destined to take rank with the leading organizations of related aim in Great Britain, France, Germany, Austria, and other countries; and that, to maintain the high character with which it starts out, it will be necessary to limit the fellowship, and that the legend indicating fellowship in the society ("F.G.S.A.") should be regarded as an honorary title. But one dissenting voice was raised against the last proposition.

The meeting of organization was concluded by an eloquent ad-

dress by the newly elected president, Professor Hall, in which he recounted the history of the development of geologic science in America from its first inception, through the informal meetings of the four State geologists of New York, for discussion of their respective observations, in 1838-40; through the organization of the American Society of Geologists, into which these informal meetings grew, in 1840; through the development of this geologic society into the most powerful scientific organization in the country, the American Association for the Advancement of Science; through the development of the various State and Federal surveys; through the various efforts made for concerted action among American geologists; and down to the completion of the organization of the present society. With every step in this half-century Professor Hall has been identified. The progress has been due to his own efforts perhaps more largely than to those of any other individual. His heart was touched, and his spirit touched, by the recognition of his decades of patient labor; and his picture of the progress of these decades was painted in glowing colors.

The next meeting of the Geologic Society of America will be held at Toronto in August next, in connection with the annual meeting of the American Association for the Advancement of Science.

The Geologic Society of America will hereafter hold regular annual meetings during the holiday week, perhaps in connection with those of the American Society of Naturalists. Biennial meetings for the presentation of papers, for the study of representative geologic areas, etc., will be held each summer in connection with the regular meetings of the American Association, beginning with the Toronto meeting in August next.

AN AUTHORITATIVE DEFINITION OF MANUAL TRAINING.

At the regular semi-annual meeting of the New Jersey Council of Education, held at Trenton, Dec. 26, 1888, a report was received from the special committee on manual training, which contained a definition of manual training. This definition was unanimously indorsed by the council, which is made up of the leading educators of the State. It has therefore more than usual significance, and, if generally adhered to, will not only place the discussion of manual training on the plane which it should occupy, but will render the discussion itself more intelligent and intelligible.

An abstract of the report is presented below. The committee charged with its preparation consisted of Dr. Nicholas Murray Butler of Paterson (chairman), Henry R. Russell of Woodbury, Superintendent C. E. Meleney (now of Somerville, Mass.), S. R. Morse of Atlantic City, and C. C. Stimets of Jersey City.

"It seems most essential at this time that some definite meaning should be attached to the phrase 'manual training,' and some action taken which would clearly indicate the opinion of the council as to exactly what 'manual training' means. It is now used in a variety of senses, and no single, definite idea is connoted by it. We hear of the 'manual-training problem,' the 'manual-training movement,' the 'manual-training school,' 'manual training in connection with geography,' and various other uses of the word, which are strangely incongruous and misleading. Some one use of the word should be selected as the proper one; and it is the opinion of the committee that this council is a body of such educational authority that it may with propriety undertake the decision of this difficult question.

"Sir Philip Magnus, an authority of much weight, says, 'By manual training one commonly means exercises in the use of tools employed in working wood and iron.' Professor Woodward of St. Louis adds to this definition the comment, 'Drawing is understood to be included in the exercises as a matter of course.' These quotations sufficiently illustrate the lack of definiteness with which the term is used even by men of high educational authority. Sir Philip Magnus defines what he means by manual training, and Professor Woodward immediately says that Sir Philip Magnus of course means to include something which he has very evidently intentionally omitted.

"Manual training was first used in this country in the sense in

which Sir Philip Magnus uses the phrase. In the report which Professor Runkle submitted to the trustees of the Massachusetts Institute of Technology, after seeing the European exhibits at the Philadelphia Exposition in 1876, he used the term in this sense; and in consequence of his argument, based in turn upon this use of the term, a school of mechanic arts was added to the courses of instruction already in operation at the institute. It is to be observed that instruction in drawing already formed part of the curriculum of the institute, and that it was not included in the term 'manual training' at the time to which we refer. When, however, the St. Louis manual-training school was founded, and later the manual-training school at Chicago, the phrase 'manual-training' was broadened sufficiently to include instruction in drawing, in addition to the instruction in the tools commonly used in working wood and iron. Judge MacArthur, Mr. Charles H. Ham, Col. Augustus Jacobson, and others who wrote and spoke on the subject of manual training about this time, also used the word in the sense just indicated.

"When, however, the principle of the manual-training school was attacked and criticised, and it became necessary to show on what grounds it could appeal to the public funds for support, it immediately became necessary to examine very critically, not alone the economic arguments which were urged in its favor, but the educational ends which it was expected to serve. It was at once claimed by its advocates that the manual-training school was not a trade school, nor a school for apprentices, but an educational institution, in which certain trades and technical occupations were called upon to furnish material to develop the mental powers of the pupils in certain directions. Immediately this position was taken, it was necessary to show what the mental powers in question were, and why they should be developed in the directions indicated. The advocates of the manual-training school were prompt to reply that that institution was only putting into practice the educational doctrines taught by Comenius and Rousseau, and those which were carried out in another sphere of educational activity by Froebel. With the mention of Froebel and the drawing upon the kindergarten and its fundamental principles for arguments in support of the manual-training school, the narrow conception and application of the word 'manual training' then in vogue broke down, and it began to be used in a much broader as well as a much truer and more significant sense. It is because some who write and speak on this subject use the phrase in its older and narrower acceptance, while others refer to it in its broader and more comprehensive sense, that the confusion to which we have above alluded exists. It seems to us that the council should note carefully the difference between the narrow and the broad use of the phrase, and we urge upon the council the advisability and necessity of giving the weight of its authority to the more liberal application of the words.

" 'Manual training,' in the narrower sense, may be defined as 'exercises in the use of tools commonly used in working wood and iron, together with instruction in drawing.' In this sense, the kindergarten; the movement for drawing and form-study in the primary and grammar schools; the movement for better and more objective methods of teaching history, geography, number, etc.; and the manual-training movement, — are all distinct. That they are, on the contrary, not distinct but closely related, and indeed interdependent, is the decided opinion of your committee. This close relation and interdependence makes the narrower significance of the term 'manual training' at this time an impossible and a wrong one, and lays the basis for the broader and more comprehensive definition. 'Manual training,' in the latter sense, is 'instruction in thought-expression by other means than verbal language and gesture.' It includes necessarily instruction in delineation and instruction in constructive work. Whether or not the tools commonly used for working wood and iron shall be employed for the purposes of giving a part of the instruction in constructive work, is a mere incident.

"We are of opinion that the educational value of proper instruction in the use of tools has been fully proven; but it is not to be supposed that the means of giving instruction in manual training will not improve and develop, as text-books, maps, and other schoolroom apparatus have improved and developed.

"That delineation and construction are natural, early, and simple modes of thought-expression, cannot be doubted, and needs no demonstration before this council. That these modes of mental activity should be trained at school, where the sense-perception, the memory, the reasoning-power, and the verbal expression of thought, are trained, also needs no demonstration. The statement must be accepted as true as soon as it is made; for the proposition that certain mental powers shall be intentionally omitted from the school-training has not as yet found any conscious defenders, though numerous cases might be cited where men have unconsciously argued in support of it.

"The powers of thought-expression by delineation and by construction are among the activities for which Froebel made so prominent a place in his kindergarten. The principle underlying the kindergarten and the manual-training school is one and the same. It must be recognized, and its application extended to the primary and grammar grades. Then we may speak of the manual-training movement and mean something definite thereby, and we may still speak of the manual-training school and mean a school which represents the principle of the manual-training movement in the instruction it offers to pupils of high-school age.

"We urge upon the council the determination to use the phrase in this sense. It is the sense which is warranted by educational history, and the only sense that views manual training as involving the application of a great pedagogic principle, and not as an attempt to improve the methods of high-school instruction alone. We therefore submit the following resolution, and recommend its adoption:—

"Whereas there are several and conflicting uses of the term 'manual training,' be it hereby

"Resolved that the New Jersey Council of Education defines 'manual training' as 'training in thought-expression by other means than gesture and verbal language, in such a carefully graded course of study as shall also provide adequate training for the judgment and the executive faculty.' This training will necessarily include drawing and constructive work, but experience alone can determine by what special means this instruction may best be given."

SCIENTIFIC NEWS IN WASHINGTON.

Sanitary Precautions in Florida. — That "Bureau of Health." — Two Other Bills. — Oil on Water. — The Ores of Nickel Mountain. — Fossil Wood. — National Geographic Society. — Philosophical Society.

Sanitary Precautions in Florida.

THE last three of the weekly health reports of Surgeon-Gen. Hamilton have presented shocking accounts of the deplorable sanitary condition of the cities of Florida, and of the general neglect of health precautions, especially in sewage, that prevails there. The correspondent of "Science" called on Gen. Hamilton, and asked some questions bearing on these reports, eliciting the following statement.

"In general terms," said Gen. Hamilton, "it should be understood that the condition of the towns in Florida, so far as investigated, has revealed a shameful neglect of the commonest sanitary precautions. In Jacksonville the sewage system is quite inadequate, the sewers having been made largely of terra-cotta pipe; and in many of the towns cesspools were constructed where the contents were allowed permanently to percolate the soil. In view of the theory concerning yellow-fever germs being in the alimentary canal and found in the excretions, the conditions existing were exactly those most favorable to the propagation of the disease. If the people of Florida would themselves obey the ordinary laws of self-preservation, and look after their own interests, they would have much less trouble with epidemics. The Federal Government is enforcing in the yellow-fever districts more radical measures than ever before known in the history of this country: establishing gratuitous public laundries for the cleansing of possibly infected bedding and clothes, and fumigating with the consent of municipalities."

That "Bureau of Health."

The following report to the secretary of the treasury, here printed

for the first time, will be likely to seal the fate of the bill which was referred to him for his judgment as to its expediency:—

TREASURY DEPARTMENT,
Office of Supervising Surgeon-General,
U. S. Marine Hospital Service,
Dec. 28, 1888.

The Hon. C. S. FAIRCHILD, Secretary of the Treasury.

Sir, — I have to report, concerning House Bill No. 11,454, that this bill, which offers a reward of \$100,000 to any person of any nationality who discovers the true germ of yellow-fever, is wrongly conceived in my judgment, and should not pass. It was recently made the subject of strong ridicule in the American Health Association, and not a word was raised in its defence. The effect of the mere introduction of the bill has been to flood the bureau with "crank" letters of every description, many of the remedies recommended being preposterous. It will be better for the government to pay the prize as a reward of merit after the discovery shall have been made and established. The history of prizes for the discovery of remedies in times past is a blot on legislation not only in our own country, but in several countries of Europe; and the rewards bestowed have generally turned out to have been improperly given. It is recommended, therefore, that the bill be indefinitely postponed.

Respectfully yours,

JOHN B. HAMILTON,
Supervising Surgeon-General, M. H. S.

Two Other Bills.

Dr. Hamilton has reported favorably on so much of House Bill No. 7,731 as provides for the establishment of a public laboratory in Washington; also on House Bill No. 11,533, providing for a board of yellow-fever commissioners to investigate the sanitary condition of foreign infected places, and to provide for the co-operation of Spain and Mexico.

House Bill No. 11,723, for the creation of a bureau of health, etc., referred to the secretary of the treasury, is reported back to the committee adversely by Dr. Hamilton, whose opinion the secretary asked. It is held that the twenty experts which the bureau would call for could not be had for two reasons: 1. Because there are no such experts whose practice has been limited to scarlet-fever, diphtheria, small-pox, and the like; 2. If there were, \$1,200 a year would not be adequate compensation.

Oil on Water.

The United States Signal Office publishes accounts of eleven vessels which report that they used oil with great effect during the hurricane off the Bahamas in November. The following are some of the reports: Bark "Auburdale" "used oil with great success, safety of vessel and lives of all on board attributed to its use, only four gallons needed;" bark "Hale," "fish-oil used in bags at Cat-heads, vessel and crew saved by its use;" brig "Hussey," "blew a hurricane, lay to, and used oil constantly, thus saving the vessel;" schooner "St. Croix," "in constant danger, but all damage prevented by timely use of oil;" barkentine "Retriever," heavy gale, "but rode it out without breaking a rope-yarn, thanks to the use of oil." The vessels seem generally to have used only a few gallons of oil each.

The Ores of Nickel Mountain.

The interesting ores of Nickel Mountain, Oregon, are described in Dr. Day's new volume of "Mineral Resources of the United States."

"The mountain has an elevation of 2,800 feet above Riddle, or about 3,600 feet above the sea. At an elevation of 1,000 feet above the valley, the nickel ores are first found; and from this height, on all sides of the mountain to the very summit, are found beds of ore covering areas from one to twenty acres, and averaging six feet in thickness. The ores are invariably found either in boulders disseminated through a highly ferruginous earth, or in a stratified bed underlain by an altered serpentine. In places the ore in these beds is not more than a foot in thickness, but in others it will run to a depth of thirty feet. Nothing like vein-formation has yet been encountered. Occurring with the nickel ores is chromic iron and chalcodonic silica. Sometimes the latter contains nickel oxides, forming the beautiful gem stone chrysoptase. Nearly all the hydrated nickel and magnesium silicates are found in greater or less quantities at these mines. No nickel minerals other than the sil-

cates have been found. The ore bodies have been developed by numerous cuts, drifts, shafts, and quarries, all of which are in ore that in bulk contains five per cent of nickel. Some two thousand tons of this class of ore are now on the various dumps. No works have yet been erected for treating the ore, but it is confidently expected that the year 1888 will see this inaugurated.

"A specimen of the unaltered country rock from Nickel Mountain was determined by Mr. George P. Merrill, of the National Museum at Washington, as chiefly olivine, with a mineral of the pyroxene group, probably bronzite. The nickel silicates found near Webster, Jackson County, N.C., are the result of the decomposition of an olivine rock, and the occurrence in southern Oregon can be similarly explained. The association with chrome ores adds to the analogy between the two occurrences.

"Lately Professor F. W. Clarke has further substantiated the view advanced by Mr. Biddle as to the genesis of these silicates of nickel, and has extended the comparison to the silicates from New Caledonia."

Fossil Wood.

In a paper read before the Biological Society, Washington, F. H. Knowlton comes to the conclusion that the fossil wood of the Potomac formation is all coniferous. It exists under two different conditions; viz., as a silicified wood, and as lignite, which, owing to the great pressure to which it has been subjected, is much metamorphosed and distorted, and is incapable of specific determination. The former, very perfectly preserved, belongs to two genera, — *Cupressinoxylon*, with four species; and *Araucarioxylon*, with a single species.

National Geographic Society.

The National Geographic Society held its annual meeting for election of officers, presentation of reports, etc., on Friday evening, Dec. 28. The secretaries and treasurer presented their annual reports, and officers were elected for the year 1889 as follows: president, Gardiner G. Hubbard; vice-presidents, H. G. Ogden, G. L. Dyer, A. W. Greely, C. Hart Merriam, A. H. Thompson; treasurer, C. J. Bell; secretaries, Henry Gannett, George Kennan; board of managers, Cleveland Abbe, Marcus Baker, Rogers Birnie, jun., G. Brown Goode, C. A. Kenaston, W. B. Powell, O. H. Tittmann, J. C. Welling.

Philosophical Society.

The Philosophical Society, Washington, elected its annual officers as follows: president, J. R. Eastman; vice-presidents, C. E. Dutton, G. K. Gilbert, G. Brown Goode, H. H. Bates; treasurer, Robert Fletcher; secretaries, W. C. Winlock, J. S. Diller; members at large of the general committee, W. H. Dall, J. H. Kidder, H. M. Paul, F. W. Clarke, C. V. Riley, R. S. Woodward, L. F. Ward, G. W. Hill, Marcus Baker.

COMMERCIAL GEOGRAPHY.

The Iron Industry in the Southern States.

In the "Report on the Mineral Resources of the United States for 1887," recently issued by the United States Geological Survey, James M. Swank gives an interesting report of the recent rapid growth of the Southern iron industry. The activity which was so conspicuous in the latter half of 1885 and in 1886 was continued in 1887 and during the first half of 1888. This activity has been chiefly displayed in the erection of blast-furnaces for the manufacture of pig-iron.

Since the beginning of 1886 there have been built in the States south of the Potomac and the Ohio Rivers twenty-one large and well-equipped furnaces, and fourteen furnaces were in course of erection in those States on July 1, 1888. The total number of furnaces which were in blast on that date, not including those of Missouri, was 109.

There was much comment in Southern newspapers concerning the probable scarcity of a supply of good coke for the new southern furnaces, and the prediction was freely made that some of the new furnaces would be compelled to remain idle until new coal-fields could be found, or fields already discovered could be developed. With the lapse of time it has been found that the supply of good coke from Southern coal-fields has fairly, if not entirely, kept pace with the increasing demand for this fuel for furnace use. New coke-ovens have been built in connection with newly opened coal-

mines, and the quality of coke obtained from the coal of some of the older mines has been improved by more careful methods of selecting the coal and making the coke. There is particularly no longer any apprehension of a scarcity of coke for the supply of the furnaces at Birmingham and in its vicinity. A great portion of the supply is furnished from the New River coal-field in West Virginia, and the Pocahontas coal-field in Virginia. The coke from these fields has been shipped to Carondelet, Mo., and Chicago, at which places it has been used in blast-furnaces in competition with Connellsville coke.

The future of the iron industry of the South appears very promising, as there are certain advantages which other parts of the United States do not enjoy. In Alabama and Tennessee, ores and fuel are found in close proximity, and unskilled labor is cheaper than in the North; but, on the other hand, much of the pig-iron made in these States must be hauled to distant markets at great expense. In fact, no section of our country possesses a monopoly of all the advantages for producing iron and steel. Pittsburg has natural gas for its rolling-mills and steel-works, and is close to the Connellsville coke-field, but it brings its ores long distances. Chicago is nearer than Pittsburg to Lake Superior ores; but it is hundreds of miles away from Connellsville coke, and it lacks natural gas as a substitute for raw bituminous coal. In New England but little iron and steel in their crude forms are now made, but the skill in their manipulation which has been accumulated in two hundred years yet remains. The iron industry of the Rocky Mountain region will always have the stimulus of a home market remote from destructive competition. There is room in almost every section of this great country for the iron and steel industries, which have in later years been so wonderfully developed, and which are destined to expand still further.

FRANCH KONGO. — In order to develop the resources of the French Kongo, it has been proposed to establish a line of steamers running between some French port, Senegambia, and Gabon-Kongo. It is estimated that the line will require an annual subsidy of \$140,000. While the Marseilles Geographical Society indorses this scheme, Lieut. Mizon, who spent many years in the interior of the colony, and to whom we owe our present knowledge of its topography, opposes it, on the ground that the trade of the colony is unable to sustain an additional line of steamers. His remarks show that the French Kongo has developed very slowly since 1870. In that year the colony embraced the Bay of Gabon and the delta of the Ogowe. Its trade amounted to \$500,000 annually. In the following years it did not increase; but, after De Brazza's exploration of the upper Ogowe, more caoutchouc and ivory were shipped. At the same time, however, the trade in dye-woods, ebony, and wax, declined on account of the devastation of the forests. The total amount of import and export in 1882 was estimated at about \$2,000,000. Since that time it has not increased. This trade is principally in the hands of an English and a German house, who have regular lines calling in all parts of any importance between Madeira and the mouth of the Kongo; and even to them the produce of the Gabon is of little importance as compared to that of other parts of the coast. The slowness of progress in the French Kongo is principally attributed to the lack of communication with the interior and the absence of factories on the head waters of the rivers. The resources of the interior must be developed, and the natives induced to sell their goods to trading-posts in the interior, which will thus be able to collect enough valuable cargo to make the trade between Europe and Gabon more remunerative. Lieut. Mizon's considerations are of special interest when compared to the actions of the Belgian Company trading with the upper Kongo. The latter concentrates all its energies upon the establishment of good communication with the upper Kongo, and to a systematic exploration of the commercial products of that region. Undoubtedly its endeavors will finally result in producing a remunerative traffic between the remote regions of Central Africa and Europe.

BOOK-REVIEWS.

Favorite Authors for Children. By Mrs. FRANCES A. HUMPHREY. Chicago and Boston, Interstate Publ. Co. 16^o.

This little book contains brief sketches of certain authors who have written more or less for young people, though only a few of

them have made a specialty of such writing. They are twelve in number, some of them still living, while others are dead, and all are Americans. Mrs. Humphrey's object in writing the book has been to give children some idea of the authors themselves as men and women rather than to criticise or describe their writings. Only a few of their more popular works are noticed at much length, the rest being merely mentioned; but many interesting anecdotes of the authors themselves are related, and all in a style that young readers will not only understand, but enjoy. Some of the authors, such as Longfellow, Bryant, Holmes, and Mrs. Stowe, are quite widely known, while others have a narrower reputation; but an author's capacity as a writer for children is not to be measured by his success in other directions. It is evident, too, that the fashion in children's books varies from age to age; for those here noticed are quite different from the Rollo books and the writings of "Peter Parley," which were in vogue forty years ago. Mrs. Humphrey's book gives portraits of all the authors mentioned, which will add greatly to its attractiveness for children; and they will perhaps wish that she had added her own to the list.

Eating for Strength; or, Food and Diet in their Relation to Health and Work. By M. L. HOLBROOK, M.D. New York, M. L. Holbrook & Co. 12°.

In this volume of only 236 pages, the author has discussed a great variety of subjects. He has attempted to combine so much of physiology as concerns digestion with a practical cook-book, and has added a chapter on the alimentary products of the vegetable kingdom. This is one of the books which, so far as we can judge, supplies no want, and its *raison d'être* is inexplicable. The physiology of digestion is much better described in all the school physiologies, and the recipes for the kitchen contain nothing that is especially new or valuable. The composition of the volume is careless, singular verbs frequently being called upon to do duty for a plural subject. There are portions of the book from which teachers could select admirable examples of how sentences should *not* be constructed. We select one of these as an illustration: "After the stomach has done all it can in the way of digesting the albuminous matter in our food, it is passed through the pyloric orifice at its end into the duodenum, in an acid condition." We do not blame the stomach for being in an acid condition, if, after having done its full digestive duty, it is passed through the pyloric orifice into the duodenum. Such treatment would be apt to "sour" the most patient organ in the body; and even the stomach, which has the reputation of being "long-suffering," might justly display its displeasure if called upon to suffer this distortion but once, and much more if asked to do it three times a day throughout a natural lifetime. Other examples of careless composition might be mentioned, but they would add nothing to the one we have selected.

The author's chemistry is equally faulty with his composition. In speaking of the carbo-hydrates, he says that they are called "carbo-hydrates" because chemically composed of carbon and water, and then follows with the remarkable statement that the chemical formula of cane-sugar is, carbon, 12; hydrogen, 11; oxygen, 11; and that of grape-sugar, carbon, 12; hydrogen, 12; and oxygen, 12.

Taken as a whole, this book is one we not only cannot recommend, but which we deem it our duty to condemn.

A Grammar of the Latin Language for the Use of Schools and Colleges. By E. A. ANDREWS and S. STODDARD. Revised by Henry Preble. Boston, Houghton, Mifflin, & Co. 12°. \$1.12.

In the thirty years since this grammar was last revised, opinions have changed somewhat as to what the contents of such a book should be, and how they should be presented. The reviser has consequently found himself driven further and further from the earlier form of the grammar, and has moulded his materials into a form corresponding better with the present state of Latin philology. Most of the old paradigms have been retained, and others have been added. In the case of the regular verb, the four conjugations are printed side by side, so that they are more easily seen to be really varieties of one conjugation, and their forms are more easily implanted in the memory than when learned in four isolated groups.

Many of the old examples also remain, and some new ones have been introduced.

The general sequence of topics has not been greatly altered, the most important changes being the following: The sections treating of word-formation have been gathered into one place, instead of being distributed among the different parts of speech in connection with their inflection; and the treatment of word-formation is made more effective by giving the pupil some insight into the processes of the growth of words instead of merely classifying derivatives according to their apparent endings. The treatment of adverbs (except their comparison), prepositions, and other particles, has been transferred partly to "Word-Formation," and partly to "Syntax." The rules of quantity have been brought into the early part of the book instead of being relegated to "Versification;" and, while the rules of agreement for adjectives and pronouns remain in their old place at the beginning of "Syntax," the rest of the syntax of such words has been postponed till after the treatment of the cases, in order to secure a more natural progression in the study of syntactic details. On account of the necessary introduction of new matter, no attempt has been made to retain the old numbering of the sections; and the book is divided only into sections and sub-sections, with occasional notes; the three kinds of divisions being distinguished by type of different sizes, the main sections sometimes consisting of two or three numbered paragraphs. This arrangement allows a most detailed reference without the use of long or complicated indications. In the matter of pronunciation the reviser makes no reference to what is known as the English method, for the reason, he says, that "the time seems ripe for sparing the teacher the necessity of choosing between a system accepted by the scholarly world as substantially correct, and one which, though still somewhat sheltered by a conservative tradition, makes the mastery of quantity and even of word-formation unnecessarily difficult.

The third declension is made less of a stumbling-block to young learners by grouping the consonant-stems simply according to their behavior toward the letter *s*, and by presenting the *z*-stems in a progressive series, showing different stages in the absorption of consonant-stem forms. Examples in the use of the subjunctive mood have been supplied with unusual copiousness, in the belief that the contemplation of examples is the surest way to acquire a feeling for the subtle differences between the subjunctive and the indicative. The reviser has evidently tried to keep in mind the needs of the beginner, and, when it has been necessary to introduce the results of modern philological research, they are stated as simply and definitively as possible. At the same time the more advanced pupil is furnished with all that is essential to his work, both at school and in college, until the time when an exhaustive grammar becomes a necessity to him. The more difficult topics are treated in such a way as to be clear, while leaving as little as possible to be unlearned when the pupil's study becomes more mature and scientific. Thus, among many things, the growing custom of German scholars in abandoning the character *j* is followed, while the distinction between *z* and *v* is retained.

The exclusion from the present edition of a mass of details, such as rare exceptions to rules and small irregularities in the linguistic usage of the less-known Latin writers, has failed to reduce the size of the book, because of the improvement in the size of the type which the publishers have been good enough to make. The large type, clear print, good paper, and neat binding make as good a setting as the learned reviser could desire for the result of his labors.

Modern Heliographic Processes. By ERNST LIETZE. New York, Van Nostrand. 8°.

THE present book had its origin in a lecture delivered by the author in 1885. On being requested to publish this lecture in the form of a pamphlet, the author extended his studies and researches, compiling the numerous recipes and suggestions scattered in journals and books, and ascertaining their value. The book is intended for the use of engineers and draughtsmen, who are so frequently in need of a good process for reproducing their drawings. After a brief theoretical introduction on the chemical and physical action of light, the author classifies the processes as processes with salts

of silver, with iron salts, with salts of chromium, and with salts of uranium. He gives practical instructions in regard to the paper to be used, the methods of sensitizing, and the trays and dishes used for the purpose, and describes various forms of printing-frames. He then proceeds to describe the numerous processes that have been suggested, and states their advantages and disadvantages. Formulæ which were found not practical, but which are recommended by reliable authorities, have also been given. The patented processes are included, although they cannot be used generally, in order to give a complete review of the subject treated. The first thousand copies of the book are accompanied by ten specimens of heliographic prints, among which the uranium and carbon prints deserve special mention. The first chapters, in which the methods of sensitizing and printing are described, are accompanied by numerous figures illustrating the instruments and processes.

When Age Grows Young. By HYLAND C. KIRK. New York, Dillingham, 16°. 50 cents.

THE author of this work published a few years ago a speculation on the possibility of not dying, in which he undertook to maintain that it was possible to prolong human physical life indefinitely; and now, in accordance with the fashion of the time, he comes before us with a romance in which he maintains the same view. The story has no very consistent plot, but contains a considerable variety of incident of a more or less interesting character. The principal personage in the story, however, who is known as Daniel Ritter, and who is the advocate of the theory of physical immortality, is by no means an agreeable character. He has some pleasing traits, and is gifted with the power of telepathy, on which some of the main incidents of the story are made to turn. But he wishes to obtain twenty thousand dollars in order to marry the girl he loves, and gets it by defrauding an insurance company. As for the possibility of not dying, which "Ritter" maintains, it depends, we are told, on certain conditions. The first is "to believe it possible;" the second, "to be in accord with the Will of the Universe;" the third, "to make the cause of humanity your own;" and "the final step is the triumph of love in life," whatever that may mean. Now, without entering into the biological objections to such a theory, we would remark that the first of these conditions seems to be the most difficult of attainment. We are told by the prophet of an older gospel that if we have sufficient faith we can remove mountains, but the difficulty with most people is to get the faith, and we apprehend that Mr. Kirk's doctrine will encounter the same obstacle. However, if any one wishes to learn about the theory, he will take an interest in reading this book; for it has at least the literary merit of being written in a good style.

The Battle of the Swash and the Capture of Canada. By SAMUEL BARTON. New York, C. T. Dillingham. 16°. 50 cents.

THIS little book is of the "Battle of Dorking" class. It purports to be an account of an attack upon New York by a British fleet in the year 1890, together with other exciting events, including the capture of Canada, which occurred in the same year. The reason for the book's existence, and the keynote of the author's rather lively tone, may be found in the dedication of the volume, which runs as follows:—

"To the senators and ex-senators, members and ex-members, of past and present Congresses of the United States of America, who, by their stupid and criminal neglect to adopt ordinary defensive precautions, or to encourage the reconstruction of the American merchant marine, have rendered all American seaport towns liable to such an attack as is herein but faintly and imperfectly described, this historical forecast is dedicated; with much indignation and contempt, and little or no respect."

The author "makes his title clear" by explaining to those of his readers not familiar with New York waters that the Swash is a straight channel, forming a sort of hypothenuse to the two sides of the main ship-channel, which bends almost at right angles at the south-west spit in the outer bay. The admiral of the British fleet selected this channel as his base of operations against New York. "Blinding buoys," torpedoes and torpedo-boats, dynamite guns and gunboats, submarine boats, and various other devices, played a

more or less important part in defending the city against the enemy. But the most effective work was done by two insignificant-looking boats,—evidently invented by the author,—which involved a new principle of marine warfare as applicable to harbor defence. These boats carried no arms or ammunition excepting a hollow steel ram containing two tons of dynamite. Almost completely submerged, and travelling at a speed of thirty miles an hour, they made for two of the most formidable of the British ironclads. When so close to their victims that there was no risk of missing the mark, the pilots of the boats, the only men remaining aboard, quietly dropped overboard, to be afterward picked up. The rams penetrate the sides of the ironclads, two explosions follow, and there is nothing left of either but fragments. Notwithstanding all this, the British fleet enters the upper bay, and at the end of two days' bombardment, the Brooklyn navy-yard, the East River bridge, and the lower part of New York City are utterly destroyed.

But the book must be read to be appreciated. It is well written and interesting, and puts into striking form the essence of the many arguments advanced from time to time for "restoring our merchant marine, strengthening our coast defences and the navy, and supplementing the latter by a naval reserve."

More about the Black Bass. By JAMES A. HENSHALL, M.D. Cincinnati, Robert Clarke & Co. 12°. \$1.50.

THIS volume is a supplement to the "Book of the Black Bass," by the same author, who is an expert angler and an eminently practical writer on black bass and bass-fishing. He has thought it best to issue this supplement in a separate volume, letting the original edition remain intact, the chapters in both volumes being so arranged as to agree in number and caption. The plan pursued in the original book, of illustrating the tools and tackle by engravings especially prepared for manufacturers, to illustrate their different lines of specialties, has been adhered to in the supplement.

The book is divided into three parts. The first part treats of the scientific history, nomenclature and morphology, general and special features, coloration, geographical distribution, habits, and intelligence and special senses of the black bass, and on stocking inland waters with them. Fishing rods, reels, lines, hooks, artificial flies, artificial and natural baits, and miscellaneous implements, receive attention in the second part. The third part is devoted to the philosophy of angling, conditions governing the biting of fish, the black bass as a game-fish, fly-fishing, casting the minnow, still-fishing, trolling, and skittering and bobbing. The volume will be welcomed by every genuine angler who "loves angling for its own sake," while even the pot-fisher, who "likes fishing for the spoils it brings," may find in it valuable hints that will increase his income.

AMONG THE PUBLISHERS.

AT last we are treated to a novelty in the way of almanac-making. Dr. J. C. Ayer & Co., the well-known manufacturers of Ayer's sarsaparilla, Lowell, Mass., send us their "Almanac for 1889," in the shape of a good-sized book, embracing editions in English, calculated for the various sections of the United States, the Dominion of Canada, India, South Africa, and Australia; also editions in nine other languages. The volume contains, also, specimen pages of pamphlets issued by the company in eleven languages not represented by the almanacs, including Greek, Turkish, Armenian, Chinese, Burmese, and Hawaiian,—twenty-one languages in all. From the preface we learn that no fewer than fourteen millions of these almanacs are printed yearly. A copy of this favorite almanac may be had at your druggist's. It is a species of "yellow covered literature" of value.

—Never without some papers which are sterling contributions to political and social science, "The Atlantic" for January has in this department "A Difficult Problem in Politics," by Frank Gaylord Cook, the problem being how to attain "uniform legislation" throughout the Union; and one of Lillie Chace Wyman's "Studies of Factory Life," this time of the relation of "The American and the Mill." Professor Shaler of Harvard University considers "The Athletic Problem in Education;" and there are papers by Philip Dymond, on "Von Moltke's Characteristics," and by John Fiske, on "Washington's Great Campaign of 1776."

— The most important article in the "Political Science Quarterly" for December is by Professor Theodore W. Dwight, on "The Legality of 'Trusts.'" The writer considers the common-law doctrine respecting restraint of trade, and other principles bearing on the question, and reaches the conclusion that trusts are partnerships, like any others, and that unless they can be shown to have been formed *with the intent* of raising prices unduly, or for some other distinctly unlawful purpose, they are lawful under the law as it now stands. He then goes on to maintain that the constitutional provision that no man shall be deprived of liberty without due process of law, forbids the State to interfere with them; or, in his own words, if the trust "is *now* lawful as a reasonable and proper element in production, it cannot properly be made unlawful by legislative acts of a stigmatizing character;" which seems rather singular doctrine. The sale of intoxicating liquors is now lawful in the State of New York; but is the Legislature forbidden by the Constitution to prohibit it? Besides this paper of Professor Dwight's, there is an article by Professor Hadley on "Public Business Management" that is worthy of attention. The writer considers the question in various aspects and with reference to recent examples, and reaches the conclusion that the management of business enterprises by the State or the city has not thus far proved very successful. On the other hand, Mr. William Clarke, in discussing "Socialism in English Politics," maintains the opposite view, and predicts the rapid growth of State socialism in England. Professor Burgess treats of the law recently passed, regulating the electoral count, by the Houses of Congress, and pronounces it nothing but a makeshift. The concluding essay in the review is by two English writers, on "The Ballot in England," and gives both a history of the subject and an account of the kind of ballot now in use there. At the present time, when the question of ballot reform has become important in America, this article will be found useful.

— The Worthington Co. have ready "Our Presidents," by Virginia F. Townsend, giving the lives of the twenty-two Presidents of the United States, enlivened by anecdotes and romantic incidents in the lives of the men who received the highest honor in the gift of their countrymen. The fine steel portraits of these men are the work of H. B. Hall & Sons, and are executed with great care. In these days of all sorts and conditions of reproduction processes, it is a rest to the eyes to see the solid steel engravings of former days once more. The publishers get out this timely work in an *édition de luxe* limited to five hundred copies, with portraits printed on India paper, and the volume is handsomely and appropriately bound in rich red cloth with title on white label.

— G. W. Smalley, in the "New York Tribune," Dec. 14, states that an interesting, even surprising fact relating to America came out at Dr. Robertson Smith's dinner to the "Encyclopædia Britannica" contributors. Mr. Black, one of the publishers, told the company the entire circulation of the new ninth edition was fifty thousand copies, of which forty thousand went to the United States; Americans, that is, have bought four times as many copies of the best English encyclopædia as the English themselves have. America has, in fact, absorbed a million quarto volumes of this great work. These figures, we presume, refer only to the editions handled in this country by Little, Brown, & Co. and Charles Scribner's Sons, and do not include the two reprints of the J. M. Stoddard Co. and of the combination using the photographic process.

— From January, 1889, when Vol. XI. will begin, "The American Chemical Journal" will appear in *eight numbers a year, instead of six as heretofore*. As far as may be practicable, one number of about seventy-two pages will be issued each month of the year, excepting July, August, September, and October. For some time past the supply of articles submitted for publication has been so great as to require the entire space of the journal, and the editor has found it impossible to continue the reviews, reports, and abstracts which formed a somewhat prominent feature of the earlier volumes. It is proposed now to restore this feature, and a strong effort will be made to secure such reviews and reports as will give a fair idea of the progress of chemistry in its various branches. In consequence of the increase of size, the price will be

raised from three dollars to four dollars a volume. Hereafter all communications in regard to subscriptions should be addressed to the *Publication Agency of the Johns Hopkins University, Baltimore, Md.*; and editorial communications, to the editor, Ira Remsen, *Post Office Drawer 2, Baltimore, Md.*

— The "Journal of Morphology" for November (Boston, Ginn & Co.) contains the following interesting articles: "On the Development of *Manicina Areolata*," by Henry V. Wilson; "The Structure and Development of the Visual Area in the Trilobite, *Phacops Rana*, Green," by John M. Clarke; "Further Studies on *Grammicolepis Brachiusculus*, Poey," by R. W. Shufeldt; "On the Relations of the Hyoid and Otic Elements of the Skeleton in the Batrachia," by E. D. Cope; and "On the Affinities of *Aphriza Virgata*," by R. W. Shufeldt.

— "Writing for Young People — Ideal," "Shorthand for Literary Purposes," "Mental Dyspepsia," "Statute Regulations for the Press," "On Quoting," and "Learning to Write," are among the topics discussed in the January number of "The Writer." This unique magazine for literary workers is now in its third volume.

— An interesting experiment in bringing up a baby without shoes and stockings is described at length in the January number of "Babyhood." The experiment was successful, but the medical editor takes occasion to protest against the "hardening process" to which some parents submit their children. "Chilblains and frost-bites" is just now a very reasonable subject, and it is not often that one finds so practical and authoritative a treatment of it as Dr. Bissell offers to the readers of "Babyhood." "Learning to Walk," by Dr. Canfield, deals with a subject of perennial interest to mothers of young children. "Home Instruction for Little Children" will be found particularly valuable in households where the nursery begins to expand into the schoolroom. The letters contributed by mothers include a vigorous protest against the absence of sleeping-car comforts for ladies and children, a rather despairing inquiry as to the limit of a mother's devotion to her children, a striking illustration of the dangers of the fruit-diet to expectant mothers, etc. The "Nursery Observations" record many amusing and curious traits of young children, and the answers to "Nursery Problems" are instructive.

— The "Quarterly Journal of Economics" for January is a university number. Professor Andrews of Cornell writes upon "Trusts;" Professor Patten of Pennsylvania, on "Capital;" Professor Hadley of Yale, on "The Railroads under the Interstate Commerce Law;" and Professor Edgeworth of King's College, London, on "The Appreciation of Gold." Harvard is represented by a copious array of notes and memoranda on various interesting topics, and a review of "The Tariff Literature of the Campaign," and an historical paper on the suspension of specie payment in Italy in 1866, written as a university study by A. B. Houghton in 1886, and now issued as an appendix to this number.

— The long-announced articles by Mr. Charles DeKay, on Ireland, begin in the January "Century;" the first being entitled "Pagan Ireland," with illustrations of the mediæval castle at Clonmiconis, the Cross at Monasterboice, the round tower at Ardmore, etc. Mr. Wilson, the photographer, continues his series on the Holy Land in connection with the International Sunday-School Lessons. The present instalment, profusely illustrated, is entitled "Round about Galilee." The Lincoln life in this number deals with three commanding events. — Pope's Virginia campaign, the battle of Antietam, and the announcement of emancipation. An illustrated article on "The West Point of the Confederacy" gives an account of a battle the details of which are little known in the North, and in which the cadets of the Virginia Military Institute at Lexington took a conspicuous and romantic part, suffering heavily in killed and wounded. An essay by Col. Auchmuty tells about a new movement in connection with the subject of American labor. This essay is entitled "An American Apprenticeship System," and describes a new system of apprenticeship, which Col. Auchmuty considers "suitable to American wants," and which he says "concerns in no small degree the welfare of the nation." Mr. Frederic Remington, the artist, himself writes as well as illustrates

an article entitled "Horses of the Plains." Mr. Kennan, in an article entitled "The Life of Administrative Exiles," presents some of the most astounding facts gathered by him in Siberia. The article is without illustrations. The writer says in introducing it, that to present a large number of closely related facts concerning this branch of the subject in the chronological order in which they were obtained would be to scatter them through half a dozen articles, and thus deprive them of much of their cumulative force and significance. He therefore groups these facts in a single paper, which necessitates a brief interruption of the narrative, and an omission, for a single number, of the illustrations. This, he remarks, enables him to deal broadly and comprehensively with one of the most interesting and important phases of the exile system. In "Topics of the Time" are discussed "Annexation, or Federation?" "Separate Municipal Elections," the question "Are We Just to our Architects?" and "A Crisis in the Copyright Agitation." "Open Letters" deal with "Lawyers' Morals," the "Life of Lincoln," and "The Mother's Right."

—In the January "Popular Science Monthly" there are four illustrated articles, one of which, "The Guiding-Needle on an Iron Ship," opens the number. In this paper, Lieut.-Commander T. A. Lyons, U.S.N., tells why the various masses of iron on shipboard interfere with the working of the compass, and explains how the trouble is remedied. "House-Drainage from Various Points of View," is the title under which Dr. John S. Billings, U.S.A., describes, with illustrations, the present condition of this complex problem. Very timely and interesting is Mr. W. H. Larrabee's copiously illustrated paper on "Sea-Lions and Fur-Seals." Two articles that will interest teachers and parents are "The Sacrifice of Education," a protest against the abuse of examinations; and "Inventional Geometry," by E. R. Shaw, which tells how geometry has been made a pleasure to pupils using the book prepared by Herbert Spencer's father. Eighteen drawings made by boys and girls in working out the problems are inserted. "Town-Life as a Cause of Degeneracy," is the subject of an instructive paper by G. B. Barron, M.D. The nature of "Genius and Talent" is described by Grant Allen in his peculiarly happy vein. W. D. Le Sueur contributes a strong article under the title "Science and its Accusers," in which he affirms that science is simply truth, and that, while men and theories may properly be criticised, opposition to science is absurd and vain. Professor Langley's address on "The History of a Doctrine" is concluded in this number. "The Suanetians and their Home," is an account, by D. W. Freshfield, of an interesting people dwelling in the Caucasus region. Some additional facts concerning "Gauss and the Electric Telegraph" are given, and the subject of the usual sketch and portrait is Rev. Moses Ashley Curtis, the North Carolina botanist. Professor C. H. A. Bulkeley, D.D., contributes a letter on "The Relation of Altruism to Egoism," criticising Mr. Smiley's recent article. The "Editor's Table" deals with "The March of Practical Science" and "The Abuse of Examinations;" and the "Miscellany" and "Notes" are varied and instructive.

—The tenth volume of the "Proceedings of the United States National Museum" has just been issued. The signatures composing the volume were issued from April, 1887, to October, 1888. Like the preceding issues, the volume contains primarily essays on zoological subjects, although others are not wanting. The greater part of the work is occupied by papers prepared by the scientific corps of the National Museum, while others treat upon the collections of the museum. In an appendix a catalogue of the contributions of the section of graphic arts to the Ohio Valley Centennial Exposition at Cincinnati is given.

—The fifth volume of the "Mineral Resources of the United States," by David T. Day, has just been issued by the United States Geological Survey. It covers the calendar year 1887. The statistical tables contained in the former volumes have been brought forward, but repetition of descriptive matter has been avoided wherever possible. The result of Professor Day's careful investigations shows an aggregate value of \$538,056,345 for the mineral industries of the United States. This is nearly \$73,000,000 more than the product in 1886, and considerably more than \$100,000,000 in

excess of the year 1885. Of many items which have contributed to this result, all the metals increased in quantity, except gold and the minor metal nickel, and nearly all increased in price. The significance of this is seen in the increased production of the fuels necessary for reducing these metals and preparing them for use. All of these fuels, including natural gas, show a marked increase. The value of building-stone increased considerably, but this apparent advance is principally due to a more careful canvass of this industry than has been possible in previous years. Professor Day does not consider it probable that the great total recorded for 1887 will be equalled in the present year.

— "A Course of Mineralogy for Young People" (Agassiz Association course) is published by G. Guttenberg, teacher of natural sciences in the Erie High School, Erie, Penn. In this course it has been attempted to present the study of stones in such a manner that any bright boy or girl over twelve years of age can, without the aid of a teacher, become a fair mineralogist, being able to examine and determine all of the more important minerals, including the ores of the useful metals.

—The new edition (1889) of "The Electricians' Directory and Handbook" is in preparation. It is published at "The Electrician" office, 1 Salisbury Court, Fleet Street, London, E.C.

—An arrangement has been made by which the "Political Science Quarterly" and "The New Princeton Review" are consolidated. The publishers of the "Political Science Quarterly" (Ginn & Co.) have purchased "The New Princeton Review," and the latter journal will be merged into the former. The political and economic questions to which "The New Princeton Review" has devoted so much of its attention, and which are engrossing more and more the attention of the public, will form, as heretofore, the special field of the "Political Science Quarterly." The point of view and method of treatment which have won for both journals such cordial recognition and such extensive support will remain unchanged. Certain features of "The New Princeton Review" which have specially commended themselves to the public will be incorporated in the "Political Science Quarterly;" and as Professor Sloane, the editor of "The New Princeton Review," will be associated in future with the work of the "Political Science Quarterly," the cause of sound politics can only gain by this union of forces.

—Laidlaw Bros. & Co., 137 West 41st Street, New York City, have just issued "The Declaration of Independence and the Constitution of the United States, in German, French, and English, in Parallel Columns," translated by A. H. Laidlaw, jun.; French and German revised by Professors Hellmrich, Schoeder, and Fezandé. The translations have been carefully made. Historical notes have been interspersed throughout the work, and an appendix supplies interesting tables on matters of permanent importance. Blank pages have been added for the reception of grammatical and historical notes, for the insertion of appropriate clippings from periodicals, and for the collection of references to interesting pages of other works.

LETTERS TO THE EDITOR.

*.*Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith.

Twenty copies of the number containing his communication will be furnished free to any correspondent on request.

The editor will be glad to publish any queries consonant with the character of the journal.

The Soaring of Birds.

To the tests proposed in "Science" (Dec. 7, pp. 267, 268) for Mr. Gilbert's ingenious hypothesis that birds, in soaring, utilize the varying velocities and directions of the horizontal air-currents at different levels, one might perhaps add this: that the inclined planes of the circles described should be observably related to the direction, etc., of the wind at the earth's surface, and of the cloud-drift above. For instance: if the upper current, relatively to the lower, was from the north, we might expect the higher side of the circle to be the north side, or else to be that side along which the bird was flying southward.

The action suggested would clearly be to some extent *efficient*, but would it also be *sufficient*? Can the gradients of velocity, etc. from level to level in air-currents far above us, be rapid enough to give the bird more than a slight assistance, although perhaps I would still avail himself of even that little help? For here is much more than "friction" to be overcome. If a hawk, weighing pound or more to every square foot of effective wing and to surface, would fall through the air with outspread motionless wings ten miles an hour, which I believe to be a low estimate, the bird to sustain his weight without muscular effort, his horizontal velocity relative to the surrounding air should be not less than fifteen miles an hour. Can it be that air-currents hundreds of feet from earth, and only a few yards apart, often differ in velocity so much as that? And yet I have seen no other theory that could in the least explain the prolonged soaring of birds, if, indeed, their wings do remain motionless. Much has been said of late, in "Science" and elsewhere, of the locking of certain wing-joints: but this admirable contrivance for relieving muscular fatigue is quite irrelevant to the present problem; for, as Mr. Gilbert has recognized, it prevents not a foot-pound of that actual work which, to prevent a fall of miles per hour, must be expended at a rate of thirty mile-pounds per hour if the bird weighs three pounds.

A naval officer, whose name I forget, once told me of an observation of his own, which, if confirmed, would remove all difficulties. Standing on deck in mid-ocean in a stiff breeze, he observed certain sea-birds hovering near him with apparently unmoving wings, though holding their own against the wind. But when they came within a few yards, he could see that the outspread wings had in reality a rapid motion of very small amplitude, almost a mere tremor. His impression was, that, though the wings had not sufficient play to present the whole wing edgewise to the air during the up-stroke, and flatwise during the down-stroke, yet the individual wing-feathers might be doing this, their vanes automatically separating and turning edgewise, opening like valves or like slats of a blind, as the wing rose, and closing up again, as it fell, by the action of the air itself. Some such action of the feathers would greatly aid this kind of flight. It is for naturalists to say how well they are adapted to it, and whether such flight might be possible while the wing-joints remained locked, and whether it might therefore be sometimes a restful change for the bird.

J. E. OLIVER.

Cornell University, Dec. 19.

Cucullaris Propatagialis in Oscinine Birds.

SOME time ago ("Science," ix. 1887, pp. 623, 624), Dr. R. W. Shufeldt announced the alleged discovery in the bird-wing, of a muscle well known as *Cucullaris propatagialis*, as being particularly characteristic of the suborder *Oscines* (or, as I call them, the superfamily *Passeroidea*), special stress being laid on its taxonomic value in distinguishing the latter from the mesomyodian *Passeres*. In a subsequent number of "Science" (x. 1887, pp. 70-72) I demonstrated that the muscle in question is particularly well developed in parrots and woodpeckers; and I also stated that I had found it, though in a rudimentary state, in some of our typical mesomyodian *Passeres*, notably in *Tyrannus tyrannus*.

Through the courtesy of Mr. Frederic Lucas, I have since been enabled to dissect a fresh specimen of the Nepal Hill-Myna (*Gracula intermedia*), a sturnine bird from India. I found the *Cucullaris propatagialis* quite as rudimentary as in the *Tyrannus* alluded to. As *Gracula* undoubtedly belongs to the *Oscines*, it has been fairly demonstrated that the muscle in question is neither peculiar to the *Oscines*, nor especially characteristic of them.

In looking further into the literature, I find, also, that Fürbringer has recorded the same muscle as being rudimentary in the following oscinine birds, — *Lamprolornis insidiator*, *Pastor roseus*, *Myiagra cerulea*, *Ixos chrysoorhoeus*, *Copsychus macrurus*, and *Turdus pilaris*, — while in many others he found it but very feebly developed.

It is evident, therefore, that this variable muscular slip has no taxonomic value whatever in the direction indicated by Dr. Shufeldt. I even doubt whether it will be found of much service in defining trenchantly even families or smaller groups, since every

graduation between the rudimentary stage and the most developed condition seems to occur within the same group unquestionably nearly related birds.

LEONHARD STEJNEGER.

Smithsonian Institution, Washington, D.C.,
Dec. 20.

Answers.

ORIGIN OF FISH IN ISOLATED PONDS. — If no one else will answer Mr. C. B. Palmer's question, let me point out that nothing is simpler than that birds, lighting on the edge of first one pond, then another, should carry on their feet the eggs, larvæ, or whatever it may be, of one to the other. In digging wells in a remote desert region in Arizona, many miles from other wells, I was first surprised to find them peopled after a short time with animals (frogs, if I forget not) which could not possibly have hopped or crawled from the nearest water, across the burning sand in mid-summer, with the thermometer rising above 115° F. But I soon saw the above easy explanation.

HENRY M. HOWE.

Boston, Dec. 22.

40. FELSPAR, OR FELDSPAR? — The note on the spelling of the word "feldspar," in "Science" of Dec. 14, is satisfactory with the exception of its closing sentence, which says that the form "felspar," although wrong, had been so long employed that "no one who prefers it can be criticised for using it." It should be added to this, that all other nations except Great Britain and her colonies, and also that ninety-nine hundredths of all mineralogical literature, spell the word with the *d* (or with the substitute *t* if the language requires it), and they do so because this is etymologically right; that the English drop the letter because the error in Great Britain has been persisted in until it has become *English*; and that such national prejudice is not a legitimate ground for scientific action even in Great Britain. Years since, the writer, thinking, like many others, uniformity in scientific nomenclature very desirable, sent a short paper, giving the British history of the word, to the "London Philological Magazine," which was accepted, and published anonymously as was requested. But national prejudice proved to be superior to all other considerations. In this country the prejudice has no right to a place, and the transplanting of its effects should not be allowed without a protest.

J. D. D.

41. THE "SUPERNUMERARY MOLAR" IN MAN. — As a partial reply to Query 41 in "Science" of Dec. 7, permit me to state that Dr. Shufeldt will find in skull No. 1327, of the Morton collection in the Philadelphia Academy of Natural Sciences, the finest specimen extant of molars posterior to the third or "wisdom" teeth. It is some years since we saw it, and then "as through a glass" only; but our recollection of it is that the superior fourth molars are quite through the alveolar process, while the inferior are just seen from above in their course to the surface. The superior fourth molars are not "peg-like," but molar-like, though smaller than their neighbors. The specimen is Australian. We have a personal acquaintance who has eighteen teeth in the upper jaw; the "extra" teeth, one on each side, posterior to the third molar or "wisdom" teeth. Like Dr. Shufeldt's specimen, these are "conical, peg-like," as to form of crown. According to dental writers, the African races seem specially favored in this matter. For the best account of this structure in man (assuming it to be "supernumerary"), reference is made to the late Dr. M. S. Dean's translation of Magitot and Segros' "Dental Follicle," in which it is made to appear that the setting of an epithelial structure, and the enamel organ, determine the fact and position of the future tooth. The same process is made to account for "supernumerary" teeth elsewhere in the maxillæ, the anterior part of the upper being particularly favored. As to its significance, facts are accumulating that seem to point to the weeding-out of the third molar or "wisdom" tooth, the number and importance of the facts being directly as civilization. Such being the case, it is unreasonable to suppose this occasionally-cropping-out fourth molar other than a reversion to a past type, and to a time in the history of man when mastication was the primary, and not as now, in the civilized world at least, a secondary function?

We cordially endorse this scheme, and will add very liberal commissions for all willing to canvass for *Swiss Cross* subscriptions. N. D. C. Hodges, 47 Lafayette Place, New York.

"The Week, one of the ablest papers on the continent."—*Descriptive America*.

ENLARGED AND IMPROVED.

THE WEEK:

A Canadian Journal of Politics, Literature, Science and Arts.

PUBLISHED EVERY FRIDAY.

\$3.00 per Year. \$1.00 for Four Months.

THE WEEK has entered on its SIXTH year of publication, greatly enlarged and improved in every respect, rendering it still more worthy the cordial support of every one interested in the maintenance of a first-class literary journal.

The independence in politics and criticism which has characterized THE WEEK ever since its first issue will be rigidly maintained; and unceasing efforts will be made to improve its literary character and increase its value and attractiveness as a journal for the cultured home. Many new and able writers are now, or have promised to become, contributors to its columns, and the constant aim of the Publishers will be to make THE WEEK fully equal to the best literary journals in Britain and the United States.

As heretofore, PROF. GOLDWIN SMITH will, from time to time, contribute articles. London, Paris, Washington and Montreal letters from accomplished correspondents will appear at regular intervals. Special Ottawa Letters will appear during the sessions of Parliament.

THE WEEK in its enlarged form will be the same as "Harpers' Weekly," and the largest paper of its class on the continent.

ONE LANGUAGE FOR THE WHOLE WORLD.

WORLD-ENGLISH:

THE UNIVERSAL LANGUAGE. 25 CENTS.

EVERY one has heard of the butcher who, after a long search for his knife, at last found it in his mouth: so speakers of English have been seeking for a universal language, when, lo! it is in their mouths. The intelligibility of English words has been obscured by a dense mist of letters. This is now dispersed by A. Melville Bell, who has already won a world-wide reputation through his invention of "Visible Speech," the great boon to deaf-mutes. Professor Bell calls this new discovery of his "World-English," and the result is a language which cannot fail to meet with acceptance, and at once supersede the supposed necessity for "Volapük," or any other artificial language. No language could be invented for international use that would surpass English in grammatical simplicity, and in general fitness to become the tongue of the world. It is already the mother-tongue of increasing millions in both hemispheres, and some knowledge of the language is demanded by all educated populations on the globe. Social and commercial necessities require that the acquisition of this knowledge shall be facilitated, and it is believed that Professor Bell's invention has removed the last impediment to English becoming the universal language, for which vague desires have long been entertained, although hitherto only futile efforts have been made.

Ex-President Andrew D. White, of Cornell University, says: "I believe that the highest interests of Christian civilization and of humanity would be served by its adoption. China and Japan would be made English-speaking peoples within fifty years, and so brought within the range of Christianizing and civilizing ideas, in the largest sense. All existing missionary work is trivial as compared with this. For your system would throw wide open those vast countries, as, indeed, all the countries of the world, to the whole current of English and American thought."

For Diffusion of English throughout the World
AS
THE UNIVERSAL LANGUAGE
This "Hand-Book of World-English" is the Complete, Simple, and Efficient Medium.
FOREIGNERS

Will Acquire, by Means of this Hand-Book, a
PERFECT PRONUNCIATION OF ENGLISH.

World-English is a Royal Road to Reading.
To Teachers of English and Modern Languages
This Hand-Book will be of Primary Importance
as a Phonetic Directory.

DEFECTS OF SPEECH

Will be Readily Corrected by Means of the Articulative Directives in this Hand-Book.

HAND-BOOK OF WORLD-ENGLISH,

25 CENTS.

The plan of this little book is altogether new. Letters and sounds are so associated, in all the exercises, that from the mere knowledge of letters a learner cannot fail to pronounce words with certainty. English reading will thus be easily acquired, whether by natives or foreigners, children or adults.

The general resemblance of World-English to Literary English is such that any reader of the latter decipheres the former at sight, or, at most, after a few minutes' study of the new letters. A like result may be anticipated for those who shall learn to read from World-English. They will transfer their power of reading to the literary form of the language, almost without effort. The orthographic aspect of words will, besides, be so fixed in the eye, by contrast, that spelling will be remembered as — what it really is — a pictorial association with words.

No special training is required to qualify teachers for using this book. The subject can even be successfully introduced in the kindergarten and the nursery. This phonetic mode of initiation in reading cannot be too strongly urged on the attention of School Boards on both sides of the Atlantic.

The ordinary orthography of each word is interlined with the World-English version throughout the Exercises and Readings.

So set down, our tongue is the best for the world to unite upon.—*Brooklyn Eagle*.

The idea of Mr. Bell has much to recommend it, and the presentation is charmingly clear.—*American Phila.*
The result is a language which cannot fail to meet with acceptance.—*Boston Traveller*.

Has the merit of great ingenuity.—*Railway Age*.
His treatise, as a study of English orthoepy, condenses the result of much thought and experience in small compass.—*The Critic*.

World-English deserves the careful consideration of all serious scholars.—*Modern Language Notes*.

World-English is the English language unburdened of its chaotic spelling.—*Popular Science Monthly*.

We commend it to the attention of teachers.—*Ottawa Globe*.

"World-English" and "Hand-Book of World-English" can be had of all booksellers, or will be sent for 50 cents, post free, by the publisher,

SOLD BY ALL DRUGGISTS.

SCIENCE

FRIDAY, JANUARY 18, 1889.

THE WHITE ELEVATED ELECTRIC RAILROAD.

THE crowded state of the streets of our great cities, and the increasing necessity of greater facilities for travelling safely through them with speed and comfort, have brought to the front many devices for solving the problem of rapid transit. One of the most recent of these is the elevated railroad lately invented by Mr. R.

which are only called into play in case of an undue oscillating or rocking motion of the car resulting from obstructions or too great speed, are safeguards against the car leaving the track. They also enable the car to pass around curves of short radii at a reasonable speed without danger of derailment.

The plan and cross-section of a box girder for supporting the main bearing rail is shown in Fig. 1. This is only one of many methods which may be used for sustaining the weights of heavy trains at high speeds; another support, shown in Fig. 2, being an I

FIG. 1.—THE WHITE ELEVATED RAILROAD.

T. White of Boston, of which we present herewith two illustrations; one being a general view of a car, with a section of the roadway, including a short curve, and the other showing some details of the truck and track. In his elevated railway system, Mr. White has embodied the results of much railroad experience and many interesting experiments. As may be seen in the illustration (Fig. 1), the track is supported by a single line of columns. The car rests upon two wheels (one at each end), instead of upon eight (four at each end), as in the ordinary passenger-car. The car is steadied horizontally by eight guide-wheels (four at each end), assisted by small rollers, one projecting from beneath each guide-wheel (Fig. 2), and having an upward bearing against the side-rails, which form the horizontal guides for the car-trucks. These guide-rollers,

beam resting upon the columns. Trusses of various forms may also be used; the method of support, as well as the height and distance apart of the supporting columns, being determined by the varying local conditions.

One difficult problem in the perfecting of this system of road was that of switching; but Mr. White claims to have not only solved the problem, but to have made the arrangement of the switch such that the track is never open, even should the switch be turned the wrong way, as the bearing-wheels can never leave the supporting-rail, and consequently the car cannot leave the track.

This system of elevated railroad, though intended primarily for an electric road, may use steam or cables. As yet, we believe, there is no road in operation constructed upon Mr. White's system,

though large working models show the feasibility of not only running trains upon such a track by any of the motive powers men-

FIG. 2.—THE GUIDE-WHEELS OF THE WHITE RAILROAD.

tioned, but also of running them safely around short curves and at high speeds.

ELECTRICAL NEWS.

Light without Heat.

PROFESSOR BRACKETT of Princeton College delivered an interesting address before the New York Electric Club some weeks ago. The part of his lecture which treated of the production of light without heat gave an admirable summary of Dr. Hertz's experiments on electro-magnetic waves, and afterwards Professor Brackett indicated the lines on which he thought it would be best to experiment to obtain practical results. Briefly the state of the case is this: light consists of electro-magnetic vibrations of a definite and very short period. In our ordinary methods of artificial illumination we produce vibrations of a period that will affect the eye, by heating particles to incandescence, the resultant vibrations being of a great number of periods, only a few of them being of use for illumination. In fact, a great deal of energy is wasted, only a very small proportion of the total appearing in a form that is useful to us. Now, the problem that is presented is to produce vibrations of the period we want, and no other; and the problem is a very difficult one to solve. In nature there are phosphorescent substances and certain insects—glow-worms, fire-flies, etc.—which are very efficient illuminants, the light produced

being accompanied by very little heat: so the problem is not impossible, and we may regard it hopefully. The most serious difficulty lies in the extreme rapidity of the oscillations required, billions of them a second,—a rapidity so great that it seems impossible to attain it by any mechanical means. Nor would it be possible to economically distribute the vibrations when they were produced.

Professor Brackett proposes to solve the problem by working it backwards, to take a beam of light, polarize it so that all of its vibrations are in one plane, and "harness that to a wire, so that it will make a current vibrate and also make the magnetic field about the wire vibrate: in other words, if you cannot do the sum, take the answer and work backwards. That is what I intend to do, and I will hint to you exactly how I propose to do it. It cannot be done with the ordinary materials employed for conductors, if it has to heat the wire. . . . We must get something that is not a conductor in the ordinary sense. I remind you that the amount of energy expended in the movement in the high vacuum tube, in the ordinary tube, where you have the most beautiful illuminations, is, in matter of fact, very small. . . . I point out to you next that there is one substance in which we have the properties of both the conductor and the non-conductor present, and there are some very hopeful indications in that. A selenium cell, which is semi-transparent, when it is joined up and a battery current is put through it, is found to have its resistance diminished immediately a flash of light falls on it. . . . Suppose we take a polarizing apparatus by which we can polarize a long web of light. It will consist of vibrations all sorted out in parallel planes by themselves. . . . Now let this polarized web of light be passed through a narrow slit so as to pass directly upon or near the conductor in which we wish to set up an alternating electric current. If the proper conductor can be found, it should have the current set up in it, and this should produce a magnetic field about it. . . . What we want is an alternating current or discharge of some sort or other, which shall enable us to produce the alternations with such frequency that the so-called conductors will break out and shine directly. . . . A dynamometer ought to be constructed which would be capable of measuring the effect. But with the ordinary opaque conductor, such frequency means confusion among the molecules, which brings about a difficulty. That is what we must get rid of."

In a subject like this, which is certain to command the attention of investigators and inventors, which gives so much promise, and in which there seems no impossibility, it is well to keep abreast of even the suggested solutions. Professor Brackett's plan seems to be to transmit light from places where the sun is shining, to other places where it is not. But it is hard to see how this plan can work successfully. Vibrations of such rapidity as those of light-waves cannot be transmitted along a conductor, for conductors would offer a practically infinite resistance to currents of such a period. They are transmitted through a dielectric simply as light; and the fact that we believe light to be an electro-magnetic disturbance does not help us to solve the problem. The transmission of light as such stands just where it did before Hertz's experiments or Maxwell's theory were published. The efficiency of transmission of the waves, however they are transmitted, is much greater as the period is increased. A wave of a period some millions of times less than that of light might be transmitted from China here without much loss, provided we did it properly, while the energy of a light-wave would be dissipated before it had gone a mile. If we wish to transmit light, we must reduce the vibrations to a greater period at the sending station, and raise them again at the receiving end; and this will be difficult. If we wish to produce light, we have little encouragement in the line of producing an electric wave of the required period by mechanical means. The period of vibration of a charge of electricity, displaced on the surface of a sphere of a centimetre radius, might be a thousand million a second; but to reach the millions of millions necessary for light, the size of the sphere would have to be decreased until it had reached molecular proportions. We have in nature, however, instances of the kind of action we wish. In glow-worms and fire-flies the results we are attempting to attain are reached, and we need not despair of a problem the solution of which is called to our attention on almost any

summer's night. But the line sketched out by Professor Brackett offers, we think, only a very slender hope of accomplishment.

NEW SECONDARY BATTERIES. — Hardly a week passes but we read of some new secondary battery that is to be introduced. This state of affairs has a promising side and an unpromising one. It shows the great need of some reliable storage-battery, and it brings out the fact that a great number of people are working at the problem of finding one. Some of these new cells compare very favorably with the older and better-known types; some of them are, in all probability, not so good. One of the newest is the Johnson battery, which is to be manufactured in Boston. Special advantages are claimed for it, but no figures are given, nor is it anywhere fully described. Two other batteries have been recently put on the market, — the Macrean and the Detroit. We hope to publish some figures as to the latter at an early date: it is a promising type of cell. It is to be hoped that a year which opens with such activity in storage-battery circles will develop some cell that will make electric traction in our crowded cities practicable.

IS A VACUUM AN ELECTRIC CONDUCTOR? — Some time ago M. Foepll made some interesting experiments on the conductivity of a vacuum; his results tending to show that a vacuum is an insulator, or, at best, its conducting-power is very small. The experiment has been described in this journal. Briefly it consisted in making a galvanometer whose coils were made of glass tubing from which the air had been exhausted, and connecting it with the secondary of an induction-coil, also constructed of glass tubing. There was no inductive effect observed when a current was sent through the primary of the coil, even when the electro-motive force induced had a value of 5,000 volts. M. Foepll concluded then that an absolute vacuum would be a non-conductor, and that ordinary vacuum-tube phenomena are caused by convection. Some of his more recent experiments tend to throw some doubt on these conclusions. He placed an exhausted tube within a solenoid through which he sent a Leyden jar discharge. Luminous phenomena took place, as in an ordinary vacuum tube provided with electrodes, at which an electro-motive force is applied. We know so little, however, of the nature of luminous discharges in vacua, that we can hardly consider the evidence of the last experiment so strong as that of the first; and while it may be possible to account for either result on the hypothesis of the non-conduction, or on that of the conduction of a vacuum, the former seems much the more probable.

ELECTRIC LIGHT IN THE PATENT OFFICE. — From the report of the secretary of the interior, we learn that arrangements were made the past year with the assistance of Lieut.-Commander Bradford of the United States Navy (among the most expert of electricians), with the Brush Electric Light Company of Cleveland, O., for the construction of the necessary machinery, and the arrangement of wires, appliances, and lamps, for the Patent Office building, in order to light it completely. The department will be able to furnish its own light at so great a diminished cost, that it is believed the saving from the average annual outlay heretofore sustained will in three years reimburse the expenditure for the plant. There are such vast piles of public papers, records, and documents in the various rooms, halls, and cellars of the department, many of these so dark as to require light throughout the day, that a mode of illumination which is consistent with their safety becomes of prime importance. It is believed that this object has been most satisfactorily secured by the arrangements made under the direction of Lieut.-Commander Bradford. Secretary Vilas avails himself of the opportunity to express his sense of obligation for the great advantage enjoyed in the generous contribution of Lieut.-Commander Bradford's expert and valuable knowledge, from which he believes the electrical equipment of the department will hardly be equalled in the country for safety and efficiency, procured upon the most economical terms.

PROFESSOR N. S. SHALER of Harvard University is in Washington, on his way to the Dismal Swamp. He will there spend a fortnight in geographical and geological researches, in order to complete an article for the next annual report of the Geological Survey.

THE OBSERVATORY HILL RAILWAY OF ALLEGHENY CITY, PENN.

THIS railway has been in continuous operation since January, 1888, as an electric road. The line is about four miles in length. For one-fourth of this distance the electric conductors are contained in a sub-surface conduit. For the remainder of the line the conductors are elevated above the roadway, being bracketed off from poles erected along one side of the street. The conduit branches from double to single track, and at the present terminus of the line there is a conduit cross-over switch from down to up track. At different points along the conduit section the conduit cuts through five other street-railway tracks belonging to other companies.

On the elevated conductor section the line is single track with seven turn-outs. Double conductors are used throughout both conduit and elevated conductor sections, neither the rails nor any part of the conduit itself being used as a part of the electric circuit.

Nowhere throughout the whole line is there a space fifty feet long where a car will stand without the brakes being applied. There are thirty-four curves on the line, not including turn-outs or switches. The maximum grade is 12½ feet in 100 feet. There is a total rise of 295 feet in 4,900 feet, with an average of about six per cent. The maximum grade of 12½ is on a reversed curve (radii 100 and 200 feet). The sharpest curve has a 35-foot radius on five-per cent grade.

The Bentley-Knight conduit system consists of a power station, — engines, boilers, and dynamo-electric machines; a conduit running the whole length of the line, containing the conductors which convey the electric current to the motors; and hanging connections (ploughs) which pass through the conduit slot, and, sliding along the conductors, maintain unbroken connection between the motors and the source of power. The electric conductors are accessible only to regular employees, furnished with special tools, while the current used, even in roads of the heaviest carrying capacity, cannot injure either life or property.

The conduit, which contains the conductors and supplies the current to the motors along the line, can be placed at any point where the opening of the slot will be below any part of the car-body. In constructing a conduit line, the iron yokes shown in the accompanying figure are set up from four to six feet apart, and the conductors set against the insulators which support them at each yoke. The electrical connection between the different lengths of conductor are then made, the slot-steels set on the yokes, and the slot-steels and yokes firmly bolted together, leaving a slot opening at the surface of the street of only five-eighths of an inch. Attention is especially directed to that form of Bentley-Knight conduit which permits the width of the slot to be regulated, the slot rails to be removed, and the conductors, insulators, and interior of the conduit to be inspected, without disturbing the pavement. The conductors are copper bars connected by expansion joints, and are of sufficient size to carry the current with a loss never greater than five per cent. The fact that the conduit can swerve from a straight line to avoid obstructions, and can be laid outside of the track wherever desired, greatly decreases the expense and difficulty of laying.

Electrical connection between the motor and the conductors in the conduit is effected by a contact-plough, which consists of a flat frame, hung from the car by transverse guides (on which it is free to slide the whole width of the car), and extending thence down through the slot of the conduit. It is so constructed as to adjust itself to all inequalities of road or conduit. This frame carries two flat insulated conductor-cores, to the lower ends of which are attached, by spring hinges, small contact-shoes, which slide along in contact with the two conductors in the conduit. At the upper ends are attached connections leading to the motor. This plough can be inserted or withdrawn through the slot at will, the spring hinges allowing the contact-shoes to straighten out into line with the conductor-cores when the plough is pulled upward. By no accident, therefore, can any thing be left behind in the conduit to obstruct succeeding cars. The plough-guides are hung on transverse axes, and are held in a vertical position by a spring-catch that gives way when the plough meets an irremovable obstruction, and allowing the plough to be thrown completely out of the conduit without injury, it being also immediately replaceable. The frame of the

BENTLEY-KNIGHT STANDARD MOTOR TRUCK, CONDUIT, AND PLOUGH (FRONT VIEW).

BENTLEY-KNIGHT STANDARD MOTOR TRUCK, CONDUIT, AND PLOUGH (REAR VIEW).

plough has wearing guards of hardened steel wherever it can touch the edge of the conduit slot; and the shoes are made of soft metal, which takes up all the wear and prevents any injury to the conductors. Two ploughs are used on each car for the sake of absolute reliability.

For suburban lines, or for small cities where the traffic does not justify the employment of the more expensive conduit system, the company furnishes its elevated conductor system. The elevated conductors can be either bracketed off from poles, or hung from wires crossing the street at any desired height above the roadway. Electrical connection between the motor on the car and the elevated conductors is maintained by means of a trolley or contact-brush and a flexible conductor.

The motor and mechanism of a car operate noiselessly, and are entirely concealed from view beneath the bottom of the car. Cars may be stopped as quickly as desired, may reverse at will, and, if derailed, can propel themselves back on the track.

The motor is controlled from either end of the car; and the driver may proceed at any speed, from a slow creep to that of twenty miles an hour.

SCIENTIFIC NEWS IN WASHINGTON.

The Archæology of the District of Columbia. — Our Future Empire. — Science and Psychos.

The Archæology of the District of Columbia.

THE Anthropological Society of Washington consists of four sections, each in charge of a vice-president, but none thus far definitely organized: viz., Section A, somatology; Section B, sociology; Section C, philology, physiology, and psychology; Section D, technology. It has of late become apparent to members interested in archæology (which is included in the last section) that this subject has received inadequate attention during the past year or two, and especially that too little attention has been given to the archæology of the District of Columbia and contiguous territory. In order to strengthen this branch of anthropology, and at the same time to stimulate local investigators, a temporary organization of Section D has been effected. At a meeting of the members of the society interested in local work, called by the vice-president of the section, Dr. O. T. Mason, last week, it was decided to combine efforts and results, with the immediate object of elucidating the history of the aboriginal inhabitants of the Potomac River as recorded in relics and early writings, and with the ultimate object of preparing and publishing a monograph on the antiquities of the District of Columbia. A committee was appointed to prepare *résumés* of existing knowledge on various phases of the subject for presentation at one of the meetings of the society in April next. This committee, which has power to add to its numbers, is as follows: geology in its relations to early man, W. J. McGee of the United States Geological Survey; paleolithic man and his remains, Thomas Wilson, curator of antiquities of the Smithsonian Institution; relics of the later aborigines, S. V. Proudfit of the Interior Department; prehistoric settlements and workshops, Dr. Elmer R. Reynolds of the Pension Office; aboriginal tribes recorded by early explorers, James Mooney of the Bureau of Ethnology.

Our Future Empire.

The event of the sixteenth regular meeting of the National Geographic Society on the 11th inst. was the presentation of an elaborate paper on "The Great Plains of Canada," by Mr. C. A. Kenaston. During several seasons of constant exploration, undertaken with the object of ascertaining the agricultural, pastoral, and other capabilities of the country, Mr. Kenaston became thoroughly acquainted with the vast expanse of plain country stretching from Hudson Bay to the foot-hills of the Rockies, and from the international boundary to the Arctic Circle. The entire tract is one uninterrupted, monotonous, grassy plain, sloping gently to the eastward and northward, diversified only by shallow lakes and broad water-ways in the east, and by shallow but steep-sided cañons of the rivers beginning in the mountains in its central and western portions. The general hydrography, the more detailed topographic features, the flora, the fauna, and the *voyageurs* of the Hudson Bay Company, — the link connecting the aborigines with the white in-

vaders who now possess the land, — were all described at length; and it was pointed out that this region, long the home of the buffalo, the wolf, the badger, and uncounted myriads of wild fowl, is the American wheat-field of the future. In the south-eastern portion of the tract the soil is a dark prairie loam, like that of Minnesota and Iowa; west and north-west of it lie millions of acres of "gumbo" soil, refractory under the first efforts of the agriculturist, but made fruitful by two or three seasons of tillage; while the soil of the northern plains is a fertile yellow loam or bowlder drift; and over twenty millions of acres the conditions of soil and climate are alike so favorable to wheat-growing, that only peopling by farmers and the opening of transportation routes are needed to make any part of it successfully rival the famous wheat-fields of Minnesota and Dakota. Already the tract is intersected by the Canadian Pacific and many other railways, the navigable rivers are being supplied with steam-craft, and the lands along railways and water-ways are generally sectionized and open to occupation; and the present prospects are that this northern expansion of the Great Plains of America will be overrun by settlement nearly as rapidly as was the part drained by the Mississippi and its tributaries.

Science and Psychos.

On Friday evening last, some thirty or forty scientific men assembled at the residence of Mr. W. A. Croffut, to "assist" at some experiments in hypnotism by that gentleman. Among those present were Professor N. S. Shaler, G. K. Gilbert, Dr. T. N. Gills, A. H. Thompson, W. C. Winrock, Col. Garrick Mallory, Gen. Adam Badeau, Major Powell, and Mr. F. M. Thorn, chief of the Coast Survey, besides several members of Congress. While one of the hypnotized sensitives was personating an aged colored preacher, he was violently seized by Major Powell, denounced as an impostor, and thrust out of the room. He seemed unconscious of the strange interruption, and the stream of his exhortation flowed on unbroken to the end, until Mr. Croffut appeared and recalled him from the trance. Major Powell then made some remarks on hypnotism and the relation of its hallucinations to other states, especially to mental abstraction and heterophemy, and the desirableness of subjecting its phenomena to scientific conditions and observation.

CENSUS OF THE DEFECTIVE CLASSES.

At the suggestion of Senator Eugene Hale, chairman of the census committee of the United States Senate, Professor A. Graham Bell addressed a letter to the committee, in which he refers to some of the results of the census of 1880, especially with reference to the relative increase of the deaf, the blind, the idiotic, and the insane within recent years, as compared with the population in the United States, and to deafness as caused by the marriage of the deaf with the deaf, and makes some suggestions as to the taking of the next census. As this communication is of considerable importance at the present time, when preparations are being made for the next census, we reproduce it here *in extenso*.

According to the census returns, the defective classes have increased 400 per cent in thirty years, while the general population of the country has simply doubled. The following table shows the relative figures at each census since 1850: —

Years.	Total Population of the United States.	Total Blind Population.	Total Deaf-and-Dumb Population.	Total Idiiotic Population.	Total Insane Population.
1850.....	23,791,876	9,794	9,803	15,787	15,610
1860.....	31,443,321	12,658	12,821	18,930	24,042
1870.....	38,553,371	20,320	16,205	24,527	37,432
1880.....	50,455,783	48,928	33,878	76,895	91,997

I have examined with care the statistics of the Tenth Census relating to the deaf-and-dumb, and find internal evidence to show that in their case there has been a real increase greater than the increase of the general population, and not simply an apparent

increase due to greater accuracy of enumeration: for, when the whole population of the United States are classified according to their age in 1880, the proportion of deaf-mutes among the younger persons is seen to be greater than among the older; indeed, it is proportionally greater as the age is younger, until quite young children are reached.

The following are the number of the deaf-and-dumb returned in the Tenth Census:—

Period when Deafness occurred.	Number of Deaf-Mutes.
At or before birth.....	12,155
After birth.....	10,318
Not stated.....	11,405
Total.....	33,878

Classification of these cases according to their age in 1880 shows that there has been an enormous increase of recent years in the numbers of the non-congenitally deaf; but this need hardly be considered as a permanent condition, for it appears to be due to an epidemic of cerebro-spinal meningitis, which will probably die away, as former epidemics have done.

The following table shows the percentage of the whole population of the United States born at each decade, and also the percentage of the congenitally deaf population:—

Period of Birth.	Total Population Living in 1880.	Congenital Deaf-Mutes Living in 1880.	Percentage of the whole Population Living in 1880.	Percentage of Congenitally Deaf Population Living in 1880.
Before 1780.....	4,016	—	0.0080	—
1781-90.....	20,863	9	0.0416	0.074
1791-1800.....	196,197	63	0.3912	0.518
1801-10.....	776,507	241	1.5482	1.983
1811-20.....	1,830,095	472	3.6488	3.883
1821-30.....	3,111,317	751	6.2033	6.179
1831-40.....	4,558,256	1,078	9.0882	8.870
1841-50.....	6,359,362	1,614	12.6992	13.280
1851-60.....	9,168,393	2,460	18.2798	20.240
1861-70.....	10,726,601	3,398	21.3866	27.958
1871-80.....	13,394,176	2,068	26.7051	17.015
Total.....	50,155,783	12,154	100.0000	100.000

These results are shown in graphical form in the following diagram. The continuous line indicates the percentage of the general population, and the broken line that of the congenitally deaf population, born at each decade.

The indications are that the congenital deaf-mutes of the country are increasing at a greater rate than the general population.

The great and sudden decrease in the numbers of deaf children born in the last decade (1871-80) is probably due to imperfect returns of deaf-mutes under ten years of age: for, though 54 per cent of all the deaf-and-dumb were deaf from birth, only 30 deaf infants were reported in the census of 1880, and only 49 between the ages of one and two, out of a total deaf-mute population of 33,878.

Statistics in my possession show that in the year 1819 deaf-mutes began to marry partners who were themselves deaf-and-dumb.

The percentage of intermarriages has continuously increased, until now not less than 90 per cent of all deaf-mutes who marry, marry partners who are themselves deaf-and-dumb.

The latest statistics collected by me include 1,443 cases of marriage. Of these 1,443 deaf-mutes, I find that 71 (or 5 per cent) had married hearing persons, and 1,372 (or 95 per cent) had intermarried among themselves.

In 1828 a deaf-mute child was born of a deaf-mute father and mother, and now such cases can be numbered by the hundred. My statistics are based upon a list of 528 deaf-mutes, mostly young, who have one or both parents deaf.

Some of these children have already married deaf husbands or wives, and deaf offspring have appeared in the third generation.

I can cite families in which the deafness has been handed down through four generations, and can give in minute detail particulars relating to a family in Maine in which congenital deaf-mutes have appeared for five successive generations in increasing numbers, and in which the younger deaf-mutes are marrying deaf-mutes.

My list of deaf children of deaf parents (all, excepting one, born before 1880) comprises 528 cases (mostly young), 91.6 of whom were deaf from birth.

Upon the assumption that 528 such cases were living when the Tenth Census was taken, we obtain the following results: 1. One person in every 1,480 of the general population was deaf-and-dumb, and one person in every 64 of the deaf-mute population was a child of deaf-mute parents; 2. One person in every 2,736 of the general population was deaf from birth, and one person in every 38 of the congenitally deaf population was a child of deaf-mute parents.

The laws of heredity indicate, that, if these deaf children should marry congenitally deaf husbands or wives, an increased proportion of deaf offspring will appear in the next generation; and that the continuous intermarriage of congenital deaf-mutes from generation to generation may ultimately result in the formation of a deaf variety of the human race in America, in which all or most of the children will be born deaf.

In these conclusions I am supported by the following American men of science, all members of the National Academy of Sciences, and most of these experts on the subject of heredity. These gentlemen are Professor Edward D. Cope, editor of the *American Naturalist*; Professor Alpheus Hyatt of Harvard University; Professor William H. Brewer of Yale University; Dr. Bowditch of Harvard University; Professor Simon Newcomb of Washington, D.C.; and Professor W. K. Brooks of Johns Hopkins University.

I would therefore urge upon the United States the importance of examining in the next census the marital relations of defective persons, and the extent to which their defects have been inherited by their offspring.

The enumeration of the defective classes is always found to be itself defective.

However perfect the classification may be, the returns of these classes will always be incomplete, on account of a natural objection to expose the defects of relatives, especially when these are very young.

Accuracy of enumeration will be promoted by eliminating from the census schedules (as far as may be possible) every question that could wound the feelings of parents or friends of afflicted persons. For example: if the enumerator approached the subject of defects by asking whether the persons enumerated were perfect in sight, hearing, mind, and body, he would be more likely to secure the information desired than if he asked a fond mother whether her child was "blind, deaf-and-dumb, idiotic, insane, maimed, crippled, bedridden, or otherwise disabled."

There are degrees in every defect, and the lesser forms are more

capable of amelioration than the graver. Classification under the graver forms tends to the exclusion of the lesser from the returns; but classification under the lesser forms would include the graver, and be less objectionable to friends, so that evasions would be fewer, and the returns more accurate and complete. For example: the blind, deaf-and-dumb, idiotic, insane, maimed, crippled, bed-ridden, and otherwise disabled, would all be returned under the head of defects in sight, hearing, mind, or body; but the converse would not necessarily be true.

The returns should include all persons laboring under disabilities of sight, hearing, mind, or body, of sufficient magnitude to prevent education in ordinary schools, lessen wealth-producing power, and incapacitate for military service.

The deaf and the blind should be grouped into a sub-class by themselves, and separated as much as possible from the other defective classes, because they are enumerated chiefly for educational purposes, whereas the others need eleemosynary care or restraint.

Public establishments for purely educational purposes should be classified as "schools," and not as "asylums." They should be included in statistics relating to the general education of the people, and excluded from those relating to charitable institutions.

Many children who cannot profitably attend ordinary public schools on account of disabilities are allowed to grow up without instruction, because parents object to send them to asylums, or institutions governed by State boards of charity.

The statistics of the Tenth Census show the following figures relating to defective children of school age (six years and under twenty-one):—

	Total in the United States.	Total in Special Schools.
Blind.....	7,768	5,534
Deaf-and-dumb.....	15,059	4,893
Idiotic.....	29,373	1,942
Insane.....	3,184	—

The term "deaf-and-dumb" is not only objectionable in itself but is incorrect, because it classifies those who belong to this class as laboring under a double disability instead of a single one.

Deaf-mutes are simply persons who are deaf from childhood; and dumbness or muteness is the result of the natural defect, and not a defect in itself. The vocal organs are not defective.

Many of the so-called deaf-and-dumb can speak. Some had acquired the art before hearing was lost, and others acquired it by instruction in school.

In the census of 1880 all persons who lost hearing before they reached the age of sixteen years are classified as "deaf-and-dumb," whether they can speak or not.

This incorrect and very objectionable classification leads to evasion and inaccurate returns.

Dumbness by itself is not a defect calling for enumeration in the census (unless, indeed, for statistical purposes and the determination of causes), for defective speech alone is not a disability that prevents instruction in ordinary schools. It does not materially lessen wealth-producing power, nor does it incapacitate the person for military service.

Persons who have not studied the subject generally fail to realize that deaf-mutes should be classified among the deaf, and not among the dumb; and enumerators, therefore, can hardly be expected to follow the classification.

For the sake of accuracy in the returns, therefore, it would be well to make defective speech a subject of inquiry in the primary schedule relating to population. The dumb who are deaf, and the dumb who are idiotic, will appear on supplementary schedules relating to the deaf or the feeble-minded; and the dumb who are neither deficient in mind nor hearing need have no special schedule of inquiry.

Special schedules relating to all the defective classes (except the dumb) should be prepared with the assistance of experts of two kinds; viz., specialists who have studied the causes of the defects,

and teachers who are familiar with the special methods of instruction necessary.

The gravity of the disabilities resulting from deafness can be ascertained from two elements: (1) the age or period of life at which the defect occurred; and (2) the amount of deafness (whether total or partial). The former element is the more important of the two, for a slight defect of hearing in an infant results in graver disabilities than total deafness occurring in adult life. For example: in the case of the deaf infant, the defect interferes with the acquisition of language through the ear, and the child remains dumb. His thoughts are carried on without words, so that a mental condition exists which is abnormal. His ignorance is so great as to be appalling; for his mind is deprived of every thing that other people have ever heard of or read about that is not derived directly from their own observation. Without special instruction, such children grow to adult life with all the passions of men and women, but without the restraining influences that spring from a cultivated understanding.

Persons who become deaf in adult life have no greater disability than the defect itself; but, where deafness occurs in childhood, incidental disabilities arise which are greater than the natural defect; but because they are incidental, and not natural, they are capable of amelioration, and even complete removal, by suitable instruction in special schools. Hence the very great importance of a correct enumeration of the young deaf children.

In the primary schedule relating to population the defective classes should be grouped together under the head of "physical and mental condition," instead of under "health," as was done in 1880. The following form is suggested for incorporation in the primary schedule relating to population:—

PHYSICAL AND MENTAL CONDITION.						
CONDITION OF—						
Sight.	Hearing.	Speech (of persons 5 or more years of age.)	The Mind.		The Body.	
			Mental Development.	Mental Health.	Bodily Condition.	Bodily Health.

Is the person [on the day of the enumerator's visit] sick or temporarily disabled, so as to be unable to attend to ordinary business or duties?
If so, what is the sickness or disability?

The enumerator should be instructed to ask whether the person has perfectly normal sight, hearing, and speech; whether the mind is normally developed and in a healthy condition; and whether the bodily condition is normal and the general health good. If the answer is "yes," the enumerator should indicate the reply by a horizontal mark (—) placed in the proper column; if "no," by a mark sloping from right to left (/); and, if the question is not answered in a satisfactory and reliable manner, the column should be left blank. If the physical or mental condition is reported as "not perfectly normal" (/), the enumerator should then inquire whether the disability is sufficiently great to prevent instruction in an ordinary school, to interfere with the acquisition of a suitable means of livelihood, and to incapacitate for military service. If the answer is "yes," he should change the negative mark (/) into a cross (x), and proceed to put the interrogatories contained in the supplementary schedule relating to the special class of defect noted.

As the supplementary schedules should be prepared with the assistance of specialists, it may perhaps not be advisable for me at the present time to refer to the details, excepting so far as to say that inquiries should be instituted relating to the causes of defects and their inheritance by offspring. The marital relations of defective persons should be noted and the results tabulated. The total number of children born to them should be recorded, and the number who died young. The record should also note the number of defective and normal offspring.

In examining the ancestry of deaf-mutes, I have had occasion to consult the original population schedules of former censuses, which are preserved in the Department of the Interior; and I have found little difficulty in tracing the families backward from census to census in the male line of ascent. If the name of the father had been given in former censuses, it might now be possible for genealogical experts to trace from these records the American ancestry of every person now living in the United States in every branch, for the name of the father would give the maiden name of females. I therefore suggest that in the census of 1890 the father's name should be noted in that part of the schedule that relates to the nativity of the parents, so that the people of the United States may leave to their descendants genealogical records from which their full ancestry may at any future time be ascertained.

MENTAL SCIENCE.

Negative Suggestions.

THE meaning of this term as applied to certain hypnotic phenomena has become quite familiar. It refers to the ignoring by the subject of a portion of his sensory experience. If told that upon awakening a certain person will be absent from the room, such a person may stand directly before him, and he will be entirely ignorant of his presence. Dr. Bernheim, in studying the details of this phenomenon (*Revue de l'hypnotisme*, December, 1888), regards the condition as of purely psychic character. The defect is not physiological. The eye sees, for the subject will not run against the "invisible" person, but the brain ignores the impressions made upon it. It refuses them a hearing. This point, that in this condition the perceptions are really present but are not allowed admittance into consciousness, Dr. Bernheim proposes to demonstrate. He tells an apt subject in the hypnotic state that on her awakening he will be gone. She is awakened, searches about, but gives no sign of recognizing Dr. Bernheim. The latter speaks to her, shouts into her ear, sticks a pin into her skin, even touches her eye with it, but all with no response. She is oblivious to all impressions coming from him. If some one else touches her with a pin, she withdraws her hand at once. To do this, she must distinguish Dr. Bernheim from the other spectators; and this involves sight.

It should be noted that this experiment will not always have the same result. If told that they will not see Dr. Bernheim, some subjects will not see him, but will hear him and feel his touch, — a condition causing them a good deal of surprise, and often leading them to infer that another person must be speaking to them, and so on. By suggesting in detail that the doctor will neither be seen, heard, nor felt, a complete anæsthesia can be established.

Returning to the former subject, Dr. Bernheim, while invisible, spoke abusive words to her; but her face betrayed no emotion. Thereupon she was hypnotized by an assistant, and given the suggestion that upon her re-awakening the doctor would again be present. Dr. Bernheim then asked what he had said to her. She denied his having been present; but he insisted, impressing upon her that she would remember all. She declares it must have been a dream, but at last with great hesitation repeats Dr. Bernheim's words, his actions, his sticking her with a pin, and so on. The latent impression can thus be revived, showing that it was physiologically recorded. It is not remembered, but by a new suggestion or great effort can be revived.

A similar experience often happens in the normal state. We are absorbed in work while conversation goes on about us. We hear nothing at the time, and we have no idea of what has been said. Later, a chance association, or what not, shows that we had really been taking in what was said, though absorbed by our own work. The proof of this power of revivification is important as an aid to the explanation of hypnotic states, and is equally valuable in the medico-legal complications that might arise from them.

FATIGUE OF SIGHT. — Experiments have recently been made showing in what order a fatigued eye recovers the power of perceiving different colors. The important factor is what color has been used to induce fatigue. If the eye has been fatigued by long exposure to red, the sensitiveness for green is the first to re-appear, then for blue, then yellow, and finally red. After a "blue-fatigue,"

the order is yellow, red, green, blue; after a "green-fatigue," the order of recovery is red, blue, yellow, green; after "yellow-fatigue," it is red, blue, green, yellow. The eye recovers last the perception of the color by which the fatigue has been induced, and first recovers the sensitiveness for the complementary color. The fatigue is in the retina, for it is an independent phenomenon in the two eyes. The point of finest vision, the fovea, requires a longer time to recover from color-fatigue than the less sensitive lateral portions of the retina. The physiological process is considered to be related to the visual purple of the rods and cones.

SENSE OF TASTE. — In the case of a patient whose entire tongue, including the large circumvallate taste-papillæ at the root of the tongue, had been removed, it was found that some power of taste remained. The sensations of sweet, bitter, and sour could be obtained by applying appropriate substances to the back of the pharynx or the stump of the tongue, though if applied to the tongue the taste was apparent only during swallowing. The taste of salt was not perceived. Though these results are not fully in harmony with previous experiments, they are helpful in localizing the tasting-powers of various portions of the mouth cavity.

ACROPHOBIA. — Among the many curious psychological experiences that are now attracting attention, the one to which the term "acrophobia" has been applied has many points of interest. It refers to an exaggerated condition of the fear when in high places. Dr. Verga has recently described the phenomena in his own case. Though by nature not at all timid, all his courage leaves him when above ground. He has palpitations in mounting a step-ladder; finds it extremely unpleasant to ride on top of a coach, or even to look out of a first-story window. His idiosyncrasy forbids him to use an elevator, and the mere thought of those who have cast themselves down from high places causes tingling all over his person. The thought of the earth spinning through space is enough to cause discomfort. He finds this fear growing upon him as sight and hearing become less acute, and what walking in high places was formerly possible for him is getting more and more difficult. A greater or less degree of this fear is undoubtedly quite common. A very intense form of it seems perfectly consistent with normal mental functions.

COLOR-BLINDNESS. — Examinations in English schools tend to bear out the opinion that color-blindness is often declared to be present, when really no organic defect, but only a poor training in the naming and distinction of colors, is apparent. Some pupils, who at first seemed unable to tell colors, could be taught to do so in a few hours. One boy always called black white, and white black, and regarded colors in general as of little importance. Of one hundred boys examined, not one could be declared color-blind; of two hundred boys who were set to arranging and matching shades, none found any difficulty after a few hours' practice; and all could distinguish ordinary colors.

NOTES AND NEWS.

PROFESSOR SHALER of Harvard has just published in the "Memoirs of the Museum of Comparative Zoology," by permission of the director of the Geological Survey, a report on the Cambrian district of Bristol County, Mass., including a discussion of twenty-three species of fossils in the lower Cambrian section, from localities previously unknown to science. The total section of Cambrian beds exposed has a thickness of about seven thousand feet, and below that section there is a pre-Cambrian series of unknown depth, but probably approaching ten thousand feet. The report includes a geological map of the district, and two plates of fossils.

— Frederick Schwatka, the noted Arctic traveller, who made the longest sledge-journey on record in search of Sir John Franklin's remains, is about to head an expedition through the hitherto unknown northern mountains of Mexico.

— Surgeon-Gen. Hamilton has gone to Chicago on official business, and will be absent from Washington for a month. He reports progress in his efforts to reduce Florida cities to a safe sanitary condition.

SCIENCE RECORDS WITH REGRET the death by consumption of Mr. Z. L. White, who for some months has served as its Washington correspondent. It occurred in Nassau, N.P., to which balmy island Mr. White fled a month ago for his health. He was one of the best-equipped and best-known of Washington correspondents. For years he had charge of the *Tribune* bureau, and later represented the interests of the *Philadelphia Press*. He became much talked about in connection with the publishing of the treaty of Washington before it was officially given out, and was imprisoned by the Senate for refusing to betray the gentleman from whom he obtained it. In addition to the meed of praise which the press of the country will accord to Mr. White for unusual enterprise and intelligent industry, we gladly bear witness that he was a careful observer and an accurate compiler of scientific news. E. J. Gibson, the Philadelphia representative of the *Press* in Washington, said to our correspondent, "I first became acquainted with Mr. White while he was the Washington correspondent of the *Tribune*, eleven years ago. I was then employed in the editorial rooms of the paper in New York, and during the time Mr. White remained connected with it I had opportunity to become well acquainted with him, and

always found him a most agreeable associate and a man of the highest honor. He worked his way up in the *Tribune* office in a comparatively short time, promotion coming as a result of his energy and ability, and in that respect he was often referred to in the office as an example for new-comers. His acquaintance with public men gave him a great advantage in the collection of news, and at a convention he was able to get at the bottom facts in a very short time. His newspaper work was so well known, both on the *Tribune* and the *Philadelphia Press*, that there is no need to speak of it. He was a studious, unassuming man, and a gentleman in every sense of the word. Few newspaper men had the confidence of so many public men, and he was never accused of betraying a confidence. His kindly manner made him friends wherever he went, and he was always cheerful and hopeful."

WE HAVE FREQUENTLY had occasion to comment upon the condition of the New York City schools during the past year. This condition, and the influences that are at work in them, have far more than local interest. At the organization of the Board of Education for 1889, which took place last week, the controlling influence of the political machines was again made manifest, and those who had hoped for some improvement in this respect were bitterly disappointed. Two members of the board, who had expressed themselves publicly as in favor of a change, deserted their colleagues at the critical moment. The most contemptible and discreditable political methods had been used to bring this result about, and it again places in the president's chair the man whose previous course we so thoroughly disapproved of in our comments at the time of the contest of last spring. It is a serious matter, also, that the great city newspapers either keep their readers in ignorance of what is going on, or else endeavor to have them sympathize with it. It is the simple fact that the New York City schools to-day are in the hands of the political spoilsmen, and they use them to provide places for themselves and their friends, and to perpetuate abuses from which they derive personal benefit. From the president of the Board of Education and the superintendent of schools, down to the very janitors, there is a mass of intrigue and chicanery which is a disgrace not only to the city of New York, but to the country.

AFRICA, ITS PAST AND FUTURE.¹

AFRICA, the oldest of the continents, containing the earliest remains of man, and the birthplace of European civilization, is the last to be explored. Long before the temples of India or the palaces of Nineveh were built, before the hanging garden of Babylon was planted, the pyramids of Cheops and Cephren had been constructed, the temples of Palmyra and Thebes filled with worshippers.

Greece owes its civilization to Egypt: its beautiful orders of architecture came from the land of the Nile. The civilization of Egypt had grown old, and was in its decay, when Rome was born. Think what a vast abyss of time separates us from the days of Romulus and Remus! And yet the pyramids of Egypt were then older by a thousand years than all the centuries that have passed since then.

For ages upon ages, Africa has refused to reveal its secrets to civilized man, and, though explorers have penetrated it from every side, it remains to-day the dark continent. This isolation of Africa is due to its position and formation. It is a vast, ill-formed triangle, with few good harbors, without navigable rivers for ocean-vessels, lying mainly in the torrid zone. A fringe of low scorched land, reeking with malaria, extends in unbroken monotony all along the coast, threatening death to the adventurous explorer. We wonder that we know so much, rather than so little, of Africa. Our ignorance of Africa is not in consequence of its situation under the equa-

¹ Annual address of Hon. Gardiner G. Hubbard, president of the National Geographic Society, at its meeting, December, 1888.

tor, for South America in the torrid zone has long been known. There the explorer easily penetrates its recesses on its great rivers, — the Orinoco, Amazon, and La Plata, — for they are navigable from the ocean far into the interior. The Amazon, 3,000 miles from its mouth, is only 210 feet above the ocean-level, and, with its branches, is navigable for 10,000 miles. Africa also has three great rivers, — one on each side of this peninsula. On the north, the Nile, the river of the past, empties into the Mediterranean Sea, but its navigation is soon interrupted by five cataracts; so that the camel, the ship of the desert, bears the wares of Europe from the foot of the first cataract far up the river, 800 miles, to Berber, whence they are again shipped by boat 2,000 miles to Gondokoro, close to the lakes Albert and Victoria Nyanza, 4,000 feet above the sea-level, 4,200 miles by water from the Mediterranean.

On the west, the Kongo, the river of the future, empties into the Atlantic Ocean under the equatorial sun; but its navigation is also impeded by successive falls extending from its mouth to Stanley Pool. Then there is almost uninterrupted navigation on the river and its tributaries for 10,000 miles. Far inland the head waters of its north-eastern branches interlace with the waters of the Nile. Another branch rises in Lake Tanganyika in eastern Africa, while the main river finds its source higher up in the mountains, north of Lake Nyassa, 5,000 feet above the sea-level. On the east the Zambezi, the great river of southern Africa, empties into the Indian Ocean opposite Madagascar. The navigation of its main branch, the Shire, is interrupted not far from the ocean. The Zambezi itself is navigable to the rapids near Tete, 260 miles from its mouth; while one or two hundred miles higher up are the mighty falls of Victoria, only exceeded in volume of water by the Niagara, and nearly equal in height.

In whatever direction Europeans attempted to penetrate Africa, they were met by insurmountable obstacles. Communication by water was prevented by falls near the mouths of great rivers. The greater part of the coast was most unhealthy, and, where not unhealthy, a desert was behind it; but these obstacles, which formerly prevented exploration, now stimulate the traveller to explore the dark continent. The modern explorations of Africa commenced one hundred years ago, when Mungo Park crossed the Desert of Sahara, and lost his life in descending the Niger. From that time to the present, travellers in ever-increasing numbers, entering Africa from every side, have undertaken its exploration. Some who have entered from the Atlantic or Pacific coasts have been lost in its wilds, and nothing heard of them for one, two, or three years, when they have emerged on the opposite coast; others have passed from the coast, and have never been heard from, stricken down by disease, or killed by the natives. Zanzibar has been a favorite starting-point for the lake region of Central Africa. Stanley started from Zanzibar on his search for Livingstone with two white men, but returned alone. Cameron set out by the same path with two companions, but, upon reaching the lake region, he was alone. Keith Johnson, two or three years ago, started with two Europeans; within a couple of months he was gone. Probably every second man, stricken down by fever or accident, has left his bones to bleach along the road. Drummond, a recent explorer of Africa, chose a route by the Zambezi and Shire Rivers as healthier and more desirable. Let us hear his experience. Early in his journey, at the missionary station of Livingstonia, on Lake Nyanza, he entered a missionary home: it was spotlessly clean; English furniture in the room, books lying about, dishes in the cupboards; but no missionary. He went to the next house: it was the school; the benches and books were there, but neither scholars nor teacher. Next, to the blacksmith shop: there were the tools and anvil, but no blacksmith. And so on to the next and the next, all in perfect order, but all empty. A little way off, among the mimosa groves, under a huge granite mountain, were graves: there were the missionaries.

The Niger is the only river in all Africa navigable any considerable distance above its mouth, by small steamers adapted to its navigation; but the Niger does not give access to the interior, as it rises within 100 miles of the ocean, and, after making a great bend around the mountains of the Guinea coast, empties into the ocean only about five degrees south of its source, after a course of 2,500 miles. Its main branch, the Benue (or "Mother of Waters"), is navigable 500 or 600 miles above its junction with the Niger. The

country through which it flows is thickly peopled and well cultivated; but the natives are fierce and warlike, and have until recently prevented any exploration of the Benue.

The Mountains of Africa.

As mountain-ranges determine the course of rivers, influence the rainfall, and temper the climate, we must understand the mountain system of Africa before we can understand the continent as a whole.

From the Red Sea to the Cape of Good Hope, successive ranges of mountains follow the coast, sometimes near, at others two or three hundred miles inland; the land, in the latter case, rapidly ascending from the coast. The only breaks in this long chain are where the Zambezi and Limpopo force their way to the Indian Ocean. High peaks are found all along these ranges.

In Abyssinia, on the Red Sea, there is a range of snow mountains 14,700 feet in height. A few hundred miles to the south-east, and near Lake Victoria Nyanza, is Kilima Ndjaro, 18,700 feet high, — the highest mountain in Africa, — and the mountains of Massal-Land, a continuation of the Abyssinian Mountains. Another range, apparently an offshoot of the long range from the Red Sea, forms a wall 100 miles long, and 10,000 feet high, on the east of Lake Nyassa, separating the waters of the lake from the Indian Ocean. This range continues to the Zambezi. South of this river the mountains rise 8,000 to 10,000 feet in height. In Cape Colony are several ranges of mountains. The highest peak is Compas Berg, 8,500 feet. West of these ranges, in the equatorial region, is an elevated plateau in which is the lake region, then other ranges, and a gradual descent towards the Atlantic. There are no continuous ranges of mountains on the western coast; but at Kamerun there is a cluster of mountains reaching an elevation of 13,100 feet; and south of Morocco some of the peaks of the Atlas Mountains reach an elevation of 12,000 to 13,000 feet, but they have little if any influence on the rainfall or temperature of the country. It will be seen from this statement that in eastern Africa are high mountain-ranges and an elevated plateau; that the land in equatorial Africa gradually descends toward the west and north-west until within one or two hundred miles of the Atlantic Ocean, when the descent is rapid to the low and unhealthy coast-lands. North of Cape Colony, in the territory claimed by Portugal, the general elevation of the interior is 3,000 feet or over, sloping towards the valley of the Kongo near the equator, then north of the Kongo rising to an elevation of about 2,000 feet, and descending to 1,200 feet at Lake Chad.

Careful computations have been made to ascertain the average elevation of the continent. The mean of the most careful estimates is a little over 2,000 feet. The interior is therefore elevated above the miasmatic influences of the coast, but exactly what effect this elevation has upon the temperature can only be ascertained after careful investigation and a series of observations. North of Guinea and Senegambia the coast is less unhealthy; but, as the Desert of Sahara extends to the ocean, the country is of little value, and is therefore left to the native tribes, unclaimed by Europeans.

In the International Scientific Series it is stated that there are in Africa about ten active volcanoes, — four on the west coast, and six on the east, — but I have not found any corroboration of this report, and think it very doubtful if there are any volcanoes now in operation. The Kilima Ndjaro and Kamerun were formerly active volcanoes, for the craters still exist. In the south the diamond-fields are of volcanic ash formation.

The lake region of Africa stretches from the waters of the Nile three degrees southward, to the waters of the Zambezi, fifteen degrees south, — a lake region unequalled, in extent and volume of water, except by our lakes. Here is the Victoria Nyanza, the queen of inland seas, 4,000 feet above the sea-level; and a long series of lakes, great and small, at equal elevation. The more striking are Bangweolo to the south-west, the grave of Livingstone, and Nyassa on the south-east. In their depths the Nile, the Kongo River, and the Shire (the main branch of the Zambezi) have their source.

The great belt of equatorial Africa, situated between the 15th parallel of north latitude and the 15th parallel of south latitude, has continuous rains, is everywhere well watered, and has a rich and fertile soil. Some portions are thickly populated, and

it is capable of sustaining a dense population. North and south of this belt there are two other belts of nearly equal width. In each of these belts there are wet and dry seasons, with abundant rain for the crops. The heaviest rainfall in the north belt is in June, while in the south belt it is in December. The rainfall gradually grows less toward the north, and also toward the south, until it ceases in the Desert of Sahara on the north, and the Desert of Kalahari on the south. On the edge of each of these deserts are Lake Chad on the north, and Lake Ngami on the south. North of the Desert of Sahara, and south of the Desert of Kalahari, there is an abundant rainfall, a healthy climate, and fertile soil. Morocco, Algiers, Tripoli, and Egypt, on the Mediterranean, are in the north region; and Zulu-Land, the Orange Free State, and Cape Colony, in the corresponding region of the south.

That portion of Africa north of the equator is three or four times greater than that south, and the Sahara Desert and Lake Chad are several times greater than the Kalahari Desert and Lake Ngami. The Sahara Desert, the waterless ocean three times as large as the Mediterranean, extends from the Atlantic Ocean to the Red Sea, broken only by the narrow valley of the Nile. It is interspersed with oases, and with the valleys of many dry streams, with some mountains 8,000 feet. It has the hottest climate in the world. Travellers tell us, that, in upper Egypt and Nubia, eggs may be baked in the hot sands; that the soil is like fire, and the wind like a flame; that in other parts of the desert the sand on the rocks is sometimes heated to 200° in the day-time, while in the following night the thermometer falls below freezing-point. In crossing the desert the traveller will hardly need a guide, for the road is too clearly marked by the bones and skeletons that point the way.

Lake Chad receives the drainage of a considerable area of country. In the dry season it has no outlet, and is then about the size of Lake Erie. In the wet season it is said to be five times as large. Its level rises by twenty or thirty feet until it overflows into the Desert of Sahara, forming a stream which runs northward for several hundred miles, and is finally lost in a great depressed plain. In the southern part of Africa the level of Lake Ngami rises and falls in a similar manner.

Through the great equatorial belt runs the Kongo, one of the wonderful rivers of the world. The more we know of this river and its tributaries, the more we are impressed by its greatness and importance. Its principal source is in the mountain-range which separates Lake Nyassa from Lake Tanganyika, between 300 and 400 miles west of the Indian Ocean; thence it runs southerly through Lake Bangweolo. On leaving this lake, it takes a north-west course, running from 12° south latitude to 2° north latitude, thence running south-westerly to the ocean, nearly 3,000 miles. The river Sankuru, its principal tributary, empties into the Kongo some distance above Stanley Pool on the south. The mouths of the Sankuru were discovered by Stanley, who was struck by the size and beauty of the river, and by the lakes which connect it by a second outlet with the Kongo; but he little realized the magnitude of the river. Even before the journey of Stanley, Portuguese explorers had crossed several large streams far to the south of the Kongo, — the Kuango, the Kassai, and the Lomami, — and explored them for several hundred miles, but were unable to follow them to their mouths. In 1885 and 1886, Wissmann and the Belgian explorers sailed up the Sankuru to the streams discovered by the Portuguese. The next largest branch is the Obangi, now called the Obangi-Welle, which flows into the Kongo, on the westerly side of the continent, a little south of the equator. An expedition organized by the Kongo Free State steamed up this river in the winter of 1887 and 1888, and solved the problem, so long discussed, of the outlet of the Welle. The expedition left the Kongo in the steamer "En Avant," Oct. 26, 1887. It passed several rapids, and steamed to 21° 55' east longitude, when it was stopped by the "En Avant" running on a rock, and the opposition of hostile natives. Here it was only 66 miles from the westernmost point on the Welle reached by Junker, and in the same latitude, each stream running in the same direction, leaving no room to doubt that the two waters unite.

The Little Kibali, which rises a little to the west of Wadelai in the mountains of Sudan, is the initial branch of this river, which bears successively the name of "Kibali," "Welle," and "Doru,"

and empties into the Kongo under the name of "Obangi," after a course of 1,500 miles.

Appropriation of Africa by Europe.

The English, French, Germans, and Belgians have within a few years planted colonies in Africa. They believe it is more for their interest to colonize Africa than to permit their surplus population to emigrate to America. In Africa the colonies must depend upon the home country, and open new fields for manufactures and commerce. These countries realize the necessity of creating new markets, if they are to continue to advance. They know that in equatorial Africa there are more than 100,000,000 people wanting every thing, even clothes.

The whole coast of Africa on the Mediterranean, Sea, the Atlantic and Indian Oceans from the Red Sea to the Isthmus of Suez, is claimed by European nations, with the exception of two or three small inhospitable and barren strips of coast. England occupies Egypt, and will hold it for an indefinite period. France has its colonies in Tripoli, Algiers, and Morocco, and on the Atlantic coast its factories in Senegambia. It seeks a route from Algiers across the desert to Lake Chad, and from Senegambia up the Senegal by steamer, thence across the country by rail to the head of navigation on the Niger, and down that river to Timbuctu.

England occupies Sierra Leone, the Gold and Slave Coasts, the delta and the valley of the Niger, and its branch the Benue. It has factories on these rivers, and small steamers plying on them, and seeks Timbuctu by the river Niger. It controls almost the entire region where the palm-oil is produced.

Timbuctu, long before Africa was known to Europe, was the centre of a large trade in European and Asiatic goods. Caravans for many hundred years have crossed the Desert of Sahara from Timbuctu north to the Mediterranean, and east to Gondokoro, carrying out slaves, gold, and ivory, and bringing back European and Asiatic goods. Sandwiched between the English possessions, Liberia struggles for existence, its inhabitants fast degenerating into barbarism.

Joining the English possessions on the Gold Coast, two degrees north of the equator, are the German possessions of Kamerun, with its high mountains and invigorating breezes; but the land at the foot is no more favorable to the European than the Guinea coast. One or two hundred miles in the interior of this part of the continent, the land rapidly rises to the tableland of equatorial Africa, rich and fertile, resembling the valley of the Kongo, possibly habitable by Europeans.

Next the French occupy the Ogowe, its branches, and the coast, and claim the country inland to the possessions of the Kongo Free State. Under M. Brazza, they have thoroughly explored the country to the river Kongo, and have established factories at Franceville and other places.

The Kongo Free State comes next. It holds on the coast only the mouth of the river, its main possessions lying in the interior. Belgium is the only country that has planted colonies inland. Like all the interior of equatorial Africa, the valley of the Kongo is well watered, has continuous rains. The land is rich and fertile, but it is practically inaccessible, and before any colonies can flourish, or any extensive commerce can be carried on, must be connected by railroad with the ocean. The Compagnie du Congo has just completed a survey for a railroad on the south side of the Kongo, from Matadi, opposite Vivi, to Stanley Pool. It did not encounter any unusual difficulties, and has submitted the plans and projects to the King of Belgium for his approval.

South of the Kongo Free State are the Portuguese possessions of Angola, Benguela, and Mossamedes. Portugal, the first country to circumnavigate Africa, and the first to colonize it, has for several centuries had factories, and carried on a large trade with Africa, exchanging clothes and blankets for slaves, gold, and ivory. The Portuguese claimed the valley of the Kongo; but their claim has been reduced, and is now bounded for a considerable distance on the north by a line running due east, and west on the 6th parallel of south latitude. They have good harbors at Loango Po, Benguela, and Mossamedes, on the Atlantic coast, and the best harbor of Africa at Delagoa Bay on the Indian Ocean. The territory they claim will, I believe, prove to be the most valuable in Africa. It is well

watered by numerous tributaries of the Kongo, and by the Zambezi and its branches. It is higher than the Kongo valley, and is therefore more healthy. Several Portuguese, English, and German travellers have crossed and recrossed this part of the continent, and the Portuguese have some small settlements on the coast and in the interior. The Portuguese of the present generation have not the

The only harbor on the coast is now held by the English; and, from the character of the country, we are not surprised that the Germans have abandoned it, for we are told that "the coast is sandy and waterless, deficient in good harbors, and devoid of permanent rivers, washed by never-ceasing surf, bristling with reefs, and overhung by a perpetual haze."

APPROPRIATION OF AFRICA BY EUROPEANS.

enterprise and trading spirit of their forefathers, and are doing very little for the settlement of the country.

South of the Portuguese possessions, England claims from the Portuguese possessions on the Atlantic to their possessions on the Pacific, including Namaqua-Land, Cape Colony, the Transvaal, and Zulu-Land. Namaqua and Damara Land, formerly claimed by the Germans, are now put down on some of the maps as claimed by them; but, excepting a small colony at Angra Pequena, it is now, I believe, all claimed by the English.

North of Zulu-Land, the Portuguese claim the coast of Zanzibar. Over Zanzibar, Germany has lately assumed the protectorate, under a treaty with the Sultan of the country, claiming the land from the ocean to the great lakes; then England again, a little to the north of Zanzibar, the rival of Germany in its claims. The English have factories north-west of Zanzibar, and a regular route up the Zambezi and Shire Rivers, with a single portage to Lake Nyassa, and a road to Lake Tanganyika. They have steamers on each of the lakes, and several missionary and trading stations. The latest news from

this part of Africa says the route to the lakes has been closed, and the missionaries and merchants murdered.

North of the English possessions, the coast to the Red Sea is barren and inhospitable, little rain and no harbors, and so worthless that it has not been claimed by any European nation. North of this region is Abyssinia on the Indian Ocean and Red Sea,—a mountainous country with deep valleys, rich and fertile, but most unhealthy. Three or four thousand feet above the level of the sea, is a healthier country, inhabited by a race of rugged mountaineers, whom it has been impossible to dispossess of their lands. On the Red Sea, Italy has a small colony at Massaua, and England a camp at Suakin. The only parts of the coast not claimed by Europeans are inhospitable, without population or cultivation of any kind.

The Belgians have spent many millions in the exploration of the Kongo and its tributaries. They have several small steamers making trips from Leopoldville up the river to Stanley Falls, and up its branches, supplying the main stations on the river and its branches. The Kongo Free State, unlike all other African colonies, is free to all. Merchants of any nation can establish factories, carry on trade, and enjoy the same privileges and equal facilities with the Belgians. The valley of the Kongo, and the plateau of the great lakes, have a similar climate and soil; but the Kongo is easier of access, provisions are cheaper, more readily obtained, the natives less warlike. The Kongo Free State will therefore be more rapidly settled than any other part of the equatorial regions excepting Cape Colony.

The trade with these countries is carried on by European companies under royal charter, with quasi-sovereign powers for ruling the country and governing the natives, as well as for trading with them. England, Germany, and Portugal subsidize steamship companies which make regular trips along the western coast, stopping at the different stations.

From this statement it will be seen that England occupies the healthiest portion of Africa (Cape Colony), the most fertile valleys (the Nile and the Niger), the richest gold-fields (Gold Coast and Transvaal); that Portugal comes next, claiming the most desirable portion of equatorial Africa north of Cape Colony and south of the Kongo, but that it is unable to colonize this country, which will inevitably fall under the control of England; that the French claim Algiers and Senegambia, and are contending with England for the trade of Timbuctu and the upper valley of the Niger; that Germany, after vain attempts to penetrate the interior from Kamerun or Angra Pequena, has planted her flag at Zanzibar, and has determined to contest with England for the lake region and the great plateaus of Central Africa; while Italy, imitating the other states, tries in vain to obtain a footing on the Red Sea, worthless if obtained.

Population.

The population of Africa is roughly estimated at 200,000,000,—about 18 to a square mile, as against 88 in Europe. It is supposed that Africa was originally inhabited by the Hottentots, or Bushmen, who are now found only in south-western Africa, and by the pygmies or dwarfs scattered about Central Africa, who, some say, belong to the same group. This group is noted for its dwarfed stature, generally under five feet; but whether their size is natural, or due to privation and scanty food, is not certainly known. The Hottentot language is distinct from any other known form of speech. They seem to have been driven from Central Africa by the Bantu. The Bantu occupy the greater part of Africa south of the equator. They probably formerly inhabited north-eastern Africa, but were driven from their homes by the Hamites. The Bantu resemble the Negro in their general character, color, and physique, but their language shows essential differences. There are countless tribes of Bantu, each tribe having its own language, yet there was originally a primeval Bantu mother-tongue, from which all the dialects of this immense region are undoubtedly derived. The idioms of this family are generally known as the altilateral class of languages. North of the Bantu are the Negroes proper, occupying the greater part of Africa between 5° and 15° north latitude. The negro tribes are multitudinous, and, though alike in their main physical features, are diverse in their speech.

North of the Negro are the Nuba Fulah group, apparently indigenous to Africa, but without any thing in common with the other indigenous groups. Their name, "Pullo," or "Fulah," means "yel-

low," and their color serves to distinguish them from the Negro. The Hottentot, Bantu, Negro, and Fulah, though distinct, have each of them the agglutinative forms of speech. The Hamites are found along the valley of the Nile and in Abyssinia. The Semitic tribes occupy the larger part of the Sudan, bounded on the east by the Nile, and on the north by the Mediterranean and northern Atlantic coast.

About one-half of the population are Negroes proper, one-fourth Bantu, one-fourth Semites and Hamites, a few Nuba Fulahs and Hottentots. There are almost innumerable tribes, speaking different languages or different dialects. Over six hundred tribes and languages have been classified by Shilo, yet each is generally unintelligible to the other. Practically speaking, there are but two great divisions among the inhabitants of Africa,—the Negroes and Bantu, occupying equatorial and southern Africa; and the Hamites and Semites of northern Africa. But there is no clear-cut line even between the Mohammedan and Negro. For many hundred years the Negroes have been taken as slaves, and carried into the north of Africa, and have furnished the harems with wives, and the families with servants. The servants are often adopted into the families, so that the Negro blood now largely predominates even among the Semites and Hamites.

A broader and more practical distinction than that of language or blood is made by the religion of the African. The Mohammedan religion was probably brought from Arabia by the Semites. They conquered the country along the coasts, and exterminated or pushed to the south the former inhabitants. Then, more slowly but steadily, Mohammedanism forced its way south by the sword or by proselyting. Within the last fifty years it has re-assumed its proselyting character, and is now more rapidly extending than at any previous time.

Its missionaries are of a race nearly allied to the Negro. They live among them, adopting their customs, and often intermarrying with them. They teach of one God, whom all must worship and obey, and of a future life whose rewards the Negro can comprehend. They forbid the sacrifice of human victims to appease the wrath of an offended deity. They forbid drunkenness. They give freedom to the slave who becomes a Moslem, and thus elevate and civilize those among whom they dwell. The Christian missionary is of a race too far above him. He is a white man, his lord and master. He teaches of things his mind cannot reach, of a future of which he can form no conception; he brings a faith too spiritual; he labors with earnestness and devotion, even to the laying-down of his life. Yet the fact remains that Christianity has produced but little impression in civilizing and elevating the people, while the influence of Mohammedanism is spread on every side.

In passing from the equator south, the tribes become more degraded. Sir Henry Maine enunciated the theory of the evolution of civilization from the lowest state of the savage. In Africa he could have found all stages of civilization; in the lowest scale, man and his mate, living entirely on the fruits of the earth, in a nude condition, his only house pieces of bark hung from the trees to protect him from the prevailing wind. The vulture guides him to where, the previous night, the lion had fallen on his prey, leaving to him the great marrow-bones of the elephant or the giraffe; his only arms a stick, belonging to no tribe, with no connection with his fellow-man, his hand against every man, the family relation scarcely recognized. His mental condition is shown by his inability to count more than two: all above that is many. It is the land of the gorilla, and there seems to be little difference between the man and the ape, and, like wild beasts, they are hunted, and shot by the Boers. In ascending the scale, the family and tribal relation appears,—a house built of cane and grass or the bark of the tree; a few flocks; skill in setting traps for game; the weapon a round stone, bored through, and a pointed stick fastened in the hole. Then come tribes of a low kind of civilization, that cultivate a little ground, having a despotic king, who has wives without limit, numbering in some cases, it is said, 3,000; wives and slaves slaughtered at his death, to keep him company and serve him in another life. With them, cannibalism is common, and of these it is said that "when the sun goes down, all Africa dances." Then come tribes of a higher civilization, where the power of the chief is limited; where iron, copper, and gold are manufactured, and trade

is carried on with foreigners; where fire-arms have been substituted for the bow and spear. Next comes the Mohammedan, and last of all, on the shores of the Mediterranean, the civilization of the French and English.

It is a curious fact that many tribes that had made considerable advance in manufacturing iron and copper, have for some time ceased manufacturing; and that some have retrograded, and have lost some of the arts they formerly possessed. This decline apparently took place after the Mohammedans had conquered North Africa, and sent their traders among the Negro tribes, who sold the few articles the Negro needed cheaper than they could manufacture them, and therefore gave up their own manufactures. Such was the effect of free trade on interior Africa. The Mohammedans also manufacture less than formerly, depending more and more upon European manufactures. The enterprise of the white races defies native competition, and stifles attempts at native manufactures; there is therefore in all Africa a great falling-off in the progress of outward culture, and the last traces of home industries are rapidly disappearing.

Slave-Trade.

One of the departments of this society is the geography of life. At the head of all life stands man: it is therefore within our province to investigate those questions which more intimately concern and influence his welfare.

Slavery and the slave-trade have, within the last two hundred years, affected African life more than all other influences combined; and this trade, with all its sinister effects, instead of diminishing, is ever increasing. It has had a marked effect not only on the personal and tribal characters of the inhabitants, but on their social organization, and on the whole industrial and economic life of the country. It has not only utterly destroyed many tribes, but it has made the condition of all the other tribes one of restless anarchy and insecurity. It has been the great curse of Africa, and for its existence the Christian nations of Europe have been and are largely responsible. The temper and disposition of the Negro make him a most useful slave. He can endure continuous hard labor, live on little, has a cheerful disposition, and rarely rises against his master.

There are two kinds of slavery, — home and foreign. The first has always prevailed in Africa. Prisoners taken in war are either sacrificed, eaten, or made slaves. Slavery is also a punishment for certain offences, while in some tribes men frequently sell themselves, or by some act become slaves. These slaves are of the same race and civilization as their masters. They are usually well treated, regarded as members of the family, to whom a son or daughter may be given in marriage, the master often preferring to keep his daughter in the family to marrying her to a stranger. This slavery is a national institution of native growth. It is said one half of the inhabitants are slaves to the other half. The horrors of the slave-trade are unknown in this kind of slavery.

In the other case the slave is torn from his home, carried to people, countries, and climates with which he is unfamiliar, and to scenes and civilization which are uncongenial, where he is the slave of a master of a different color and of another and higher civilization, where the master and slave have nothing in common. The Spaniards made slaves of the Indians of America, but they were incapable of work, unfitted for slavery, and rapidly faded away. In pity for the Indians, the Africans were brought to supply their places. Their ability to labor was proved, and they were soon in great demand.

The slave-trade, as a regular commercial business, is said to have originated from a patent of Charles V. to one of his favorites, granting the exclusive right to transport 4,000 Negroes annually to the Spanish possessions in America. The patent was sold to some Genoese merchants for 25,000 ducats. The business was profitable; and respectable companies were formed in other countries to carry on a trade, protected and sometimes subsidized by the government.

In 1619 a Dutch company sent a cargo of slaves to Jamestown, Va., and thus slavery commenced in the United States. The Parliament of Great Britain incorporated the African Company of England; and by the Treaty of Utrecht, A.D. 1715, a contract for

supplying the Spanish colonies with slaves was transferred to Great Britain, and sold to the English African Company, which held the monopoly for over thirty years.

The Portuguese Company of Guinea, in 1701, contracted to furnish 10,000 "tonnes" of Negroes a year for the Spanish Main. The higher the civilization, the more cruel the master; and in no country does the slave seem to have fared worse than in Jamaica, for while the slave-trade lasted the slaves were worked to death. In one hundred years prior to 1807, when the slave-trade was abolished, 270,000 female, and 330,000 male slaves, or 600,000 in all, were imported into Jamaica. If the slave population had increased as the Negroes have increased in Jamaica since the Emancipation, the number in 1807 should have exceeded 1,000,000: it was in reality only 320,000. Although the slave-trade was abolished, it was still carried on clandestinely. When slavery was abolished in 1837, the Negro population was 300,000: in 1881 it was 600,000. Since the abolition of slavery, work has almost entirely ceased; and Jamaica, from being one of the wealthiest of islands, has become one of the poorest. But the Negro population, instead of decreasing as in slavery times, has rapidly increased.

It is impossible to ascertain the number of slaves imported into America. The estimates vary from 4,000,000 to 5,000,000. The larger number is probably an underestimate. These figures do not represent the number shipped from Africa, for 12½ per cent were lost on the passage, one-third more in the "process of seasoning;" so that, out of 100 shipped from Africa, not more than 50 lived to be effective laborers.

Livingstone, who studied the question of slavery most carefully, estimated, that, for every slave exported, not less than five were slain or perished, and that in some cases only one in ten lived to reach America. If the lowest estimate is taken, then not less than 20,000,000 Negroes were taken prisoners or slain to furnish slaves to America. No wonder that many parts of Africa were depopulated.

Though the slave-trade with America has been suppressed, thousands are annually stolen and sold as slaves in Persia, Arabia, Turkey, and central and northern Africa. Wherever Mohammedanism is the religion, there slavery exists; and to supply the demand the slave-trade is carried on more extensively and more cruelly to-day than at any previous time. The great harvest-field for slaves is in Central Africa, between 10° south and 10° north latitude. From this region caravans of slaves are sent to ports on the Indian Ocean and the Red Sea, and thence shipped to Indo-China, the Persian Gulf, Arabia, Turkey in Asia, and even to Mesopotamia, wherever Mussulmans are found. The English at Suakin are a constant hindrance to this traffic; and therefore Osman Digma has so often within the past five years attacked Suakin, and endeavored to take it from the English to hold it as a port from which to ship slaves to Arabia. Other caravans are driven across the desert to Egypt, Morocco, and the Barbary States. Portuguese slave-traders are found in Central Africa, and, though contrary to law, deal in slaves, and own and work them in large numbers. Cameron says that Alrez, a Portuguese trader, owned 500 slaves, and that to obtain them, ten villages, having each from 100 to 200 souls, were destroyed; and of those not taken, some perished in the flames, others of want, or were killed by wild beasts. Cameron says, "I do not hesitate to affirm that the worst Arabs are angels of mercy in comparison to the Portuguese and their agents. If I had not seen it, I could not believe that there could exist men so brutal and cruel, and with such gayety of heart." Livingstone says, "I can consign most disagreeable recollections to oblivion, but the slavery scenes come back unbidden, and make me start up at night horrified by their vividness."

If the chief or pacha of a tribe is called upon for tribute by his superior, if he wishes to build a new palace, to furnish his harem, or fill an empty treasury, he sends his soldiers, armed with guns and ammunition, against a Negro tribe armed with bows and spears, and captures slaves enough to supply his wants.

The territory from which slaves are captured is continually extending; for, as soon as the European traveller has opened a new route into the interior, he is followed by the Arab trader, who settles down, cultivates the ground, buys ivory (each pair of tusks worth about \$500 at Zanzibar or Cairo); who invites others to come,

and when they have become acquainted with the country, and gathered large quantities of ivory, and porters are wanted to carry the tusks to the coast, a quarrel is instigated with the Negroes, war declared, captives taken,—men for porters, women for the harem,—the villages are burned, and the caravan of slaves and ivory takes its route to the coast, where all are sold. We are told on good authority that during the past twenty years more slaves have been sent out than formerly were exported in a century. Wissmann tells us what he has seen:—

“In January, 1882, we started from our camp,—200 souls in all,—following the road, sixty feet wide, to a region inhabited by the Basonge, on the Sankuru and Lomami Rivers. The huts were about twenty feet square, divided into two compartments, the furniture consisting of caned wooden stools; floor, ceiling, and walls covered with grass mats. Between the huts were gardens, where tobacco, tomatoes, pine-apples, and bananas were grown. The fields in the rear down to the river were cultivated with sweet-potatoes, ground-nuts, sugar-cane, manioc, and millet. Goats and sheep and fowls in abundance, homestead follows homestead in never-ending succession. From half-past six in the morning, we passed without a break through the street of the town until eleven. When we left it, it then still extended far away to the south-east. The finest specimens in my collection, such as open-work battle-axes inlaid with copper, spears, and neat utensils, I found in this village.

“Four years had gone by, when I once more found myself near this same village. With joy we beheld the broad savannas, where we expected to recruit our strength and provisions. We encamped near the town, and in the morning approached its palm-groves. The paths were no longer clean, no laughter was heard, no sign of welcome greeted us. The silence of death breathes from the palm-trees, tall grass covers every thing, and a few charred poles the only evidence that man once dwelt there. Bleached skulls by the roadside, and the skeletons of human hands attached to the poles, tell the story. Many women had been carried off. All who resisted were killed. The whole tribe had ceased to exist. The slave-dealer was Sayol, lieutenant of Tippto-Tip.”

Sir Samuel Baker was largely instrumental in the suppression of the slave-trade, and, while the rule of the English and French in Egypt was maintained, slavery was greatly diminished; but, since the defeat and death of Gen. Gordon, the slave-trade has rapidly increased, and is now carried on more actively than at any other time. The only obstacles to this traffic are the presence of Emin Pacha at Wadelai, the English and American missionaries, and English trading-stations on Lakes Victoria Nyanza and Tanganyika.

The slave-traders unite in efforts to destroy Emin Pacha, and to expel the missionaries and all European traders, except the Portuguese, and for this purpose excite the hostility of the Negro against the foreigner. In this they are aided by the Mahdi. The work of the Mahdi is largely a missionary enterprise. The derishes who accompany his army are religious fanatics, and desire the overthrow of the Christians and Emin Pacha as earnestly as the slave-trader. Religious fanaticism is therefore united with the greed of the slave-trader to drive out the Christians from the lake region.

Aroused by these reports, and influenced by these views, Cardinal Lavigerie, last summer, started a new crusade in Belgium and Germany against slavery and the slave-trade. The cardinal has organized societies, and is raising a large fund to equip two armed steamships for Lake Tanganyika and Lake Nyassa, the headquarters of the slave-trade, and offers, if necessary, to head the band himself. The Pope has engaged in the work, and has sent Catholic missionaries to Central Africa. The slave-trade is carried on with arms and ammunition furnished by all the European traders. Without these arms, the slave-trade could not be successfully carried on, for the Negroes could defend themselves against slave-traders armed like themselves. While the demand for slaves continues, the slave-trade will exist, and will not cease until the factories of European nations are planted in the interior of Africa.

Mineral Wealth of Africa.

We are told in Phillips's "Ore Deposits" that the precious

metals do not appear to be very generally distributed in Africa. I believe that more thorough research will show that this view is incorrect, and that there are large deposits of iron, copper, gold, and other metals in many parts of the continent. Gold is found on the Gold Coast, in the Transvaal, in the Sudan, and in Central Africa, but only worked in surface diggings, excepting in the Transvaal; but near all these washings, gold nuggets of large size, and the quartz rock, have been discovered. In Transvaal the mines were worked a long time ago, probably by the Portuguese, then abandoned and forgotten. Recently they have been rediscovered, and worked by the English. In the Kaap gold-field in the Transvaal, three years ago, the lion and zebra, elephant and tiger, roamed undisturbed in the mountain solitudes, where there is now a population of 8,000, with 80 gold-mining companies, having a capital of \$18,500,000, one-third of which is paid up. Barberstown, the chief mining-town, has two exchanges, a theatre, two music-halls, canteens innumerable, several churches and hotels, four banks, and a hospital. A railroad was opened in December, 1887, from the Indian Ocean towards these mines, 52 miles, and is being rapidly constructed 100 miles farther to Barberstown.

There is reason to believe that gold deposits equal to those of Mexico or California will yet be found in several parts of Africa. Copper is known to exist in the Orange Free State, in parts of Central and South Africa, and in the district of Katong, southwest of Lake Tanganyika, which Dr. Livingstone was about to explore in his last journey. Rich copper ores are also found in the Cape of Good Hope, Abyssinia, and equatorial Africa. Large and excellent deposits of iron ore have been found in the Transvaal and in Algiers, and a railroad 20 miles long has been built to carry it from the Algerian mines to the sea. Very many tribes in equatorial and Central Africa work both iron and copper ores into different shapes and uses, showing that the ore-beds must be widely distributed.

One of the few large diamond-fields of the world is found in Griqua and Cape Colony, at the plateau of Kimberly, 3,000 feet above the sea. The dry diggings have been very productive; this tract, when first discovered, being almost literally sown with diamonds.

Coal has been found in Zulu-Land, on Lake Nyassa, and in Abyssinia. The latter coal-field is believed to be secondary. Iron, lead, and zinc, and other minerals, have been found in the Orange Free State. Salt-beds, salt-fishes, salt-lakes, and salt-mines are found in different parts of Africa.

Railroads.

The peculiar formation of Africa, its long inland navigation, interrupted by the falls near the mouths of its large rivers from connection with the ocean, renders it necessary to connect the ocean with the navigable parts of the rivers by railroads.

The Belgians will soon construct a railroad on the southerly side of the Kongo, to the inland navigable waters of the Kongo at Leopoldville, following the preliminary surveys lately completed; the French may also construct a road from the coast to Stanley Pool; and by one or the other of these routes the interior of Africa will be opened.

South of the Kongo, the Portuguese are constructing a railroad from Benguela into the interior. In Cape Colony railroads have been constructed in different directions, connecting the greater part of the British possessions with the Cape of Good Hope. They are also constructing a railroad from Delagoa Bay to the mines in Transvaal.

Sudan and the upper waters of the Nile can only be opened to a large commerce by a railroad from Suakin to Berber, about 280 miles. Surveys were made for this road, and some work was done upon it, just before Gen. Gordon's death. The navigation of the Nile above Berber is uninterrupted for many hundred miles. Below Berber the falls interrupt the navigation. The route from Gondokoro down the Nile is by boat to Berber, camel to Assuan, boat to Siut, and railroad to Cairo and Alexandria, making a route so circuitous that it prevents the opening of the Sudan to any extensive commerce.

In Algiers there are 1,200 miles of railroad, and more are being constructed. The French are also constructing a railroad from

the upper part of the Senegal River to the head waters of the Niger. The English have organized a company to construct a road from the Gold Coast to the mines in the interior.

It will thus be seen that the railroad has already opened a way into Africa that is sure to be carried on more extensively.

Stanley Expedition.

There are two methods of exploring Africa. One is where an individual, like a Livingstone or a Schweinfurth, or Dr. Junker, departs on his journey alone. He joins some tribe as far in the interior, on the line of exploration, as possible; lives with the tribe, adopting its habits and manner of life, learning its language, making whatever explorations he can; and, when the region occupied by such tribe has been fully explored, leaves it for the next farther on. This plan requires time and never-failing patience; but in this way large portions of Africa have been explored. The other way, adopted by Cameron, Stanley, Wissmann, and the Portuguese explorers, has been to collect a party of natives, and at their head march across the continent.

"An immense outfit is required to penetrate this shopless land, and the traveller can only make up his caravan from the bazaar at Zanzibar. The ivory and slave traders have made caravanning a profession, and every thing the explorer wants is to be found in these bazaars, from a tin of sardines to a repeating-rifle. Here these black villains the porters—the necessity and despair of travellers, the scum of slave-gangs, and the fugitives from justice from every tribe—congregate for hire. And if there is any thing in which African travellers are for once agreed, it is, that for laziness, ugliness, stupidity, and wickedness, these men are not to be matched on any continent in the world." Upon such men as these Stanley was obliged to depend.

Though travelling in this way is more rapid than the other, it is very expensive, and has many difficulties not encountered by the solitary traveller. The explorer always goes on foot, following as far as possible the beaten paths. A late traveller says: "The roads over which the land-trade of equatorial Africa now passes from the coast to the interior are mere footpaths, never over a foot in breadth, beaten as hard as adamant, and rutted beneath the level of the forest-bed by centuries of native traffic. As a rule, these foot-paths are marvellously direct. Like the roads of the old Roman, they move straight on through every thing,—ridge and mountain and valley,—never shying at obstacles, nor anywhere turning aside to breathe. No country in the world is better supplied with paths. Every village is connected with some other village, every tribe with the next tribe, and it is possible for a traveller to cross Africa without being once out of a beaten track."

But if the tribes using these roads are destroyed, the roads are discontinued, and soon become obstructed by the rapid growth of the underbrush; or, if the route lies through unknown regions outside the great caravan-tracks, the paths are very different from those described by Mr. Drummond, for the way often lies through swamps and morass, or thick woods, or over high mountain-passes, or is lost in a wilderness of waters.

The great difficulty in these expeditions is to obtain food. As supplies cannot be carried, they must be procured from the natives. Very few tribes can furnish food for a force of six hundred men (the number with Stanley); and when they have the food, they demand exorbitant prices. Often the natives not only refuse food to the famished travellers, but oppose them with such arms as they have; and then it is necessary, in self-defence, to fire upon them.

The greatest difficulty the explorer meets comes either directly or indirectly from the opposition of the slave-trader. Formerly the slave-trader was not found in equatorial Africa; but, since the explorer has opened the way, the slave-trader has penetrated far into the interior, and he is continually throwing obstacles in the way of the entry of Europeans into Africa. When it was decided that Stanley should relieve Emin Pacha, he was left to choose his route. He met Schweinfurth, Junker, and other African travellers, in Cairo. They advised him to go by his former route directly from Zanzibar to the Victoria Nyanza. The dangers and difficulties of this route, and the warlike character of the natives, he well knew. The route by the Kongo to Wadelai had never been travelled, and he thought the difficulties could not be greater than by the old route; and, beside,

he proceeded much farther into the interior by steamer on the Kongo, which left a much shorter distance through the wilderness than by the Zanzibar route. On arriving at Zanzibar, he made an arrangement with Tippoo-Tip, the great Arab trader and slave-dealer, for a large number of porters. They sailed from Zanzibar to the Kongo, where Stanley arrived in February, 1887. He then sailed up the Kongo, and arrived in June at the junction of the Aruvimi with the Kongo, a short distance below Stanley Falls. Stanley believed that the Aruvimi and the Welle were the same stream, and that by following up this river he would be on the direct route to Wadelai. Subsequent investigations have shown that he was mistaken. About the 1st of July he left the Kongo, expecting to reach Emin Pacha in October, 1887. No definite information has been received from him from that time to the present. He left Tippoo-Tip in command at Stanley Falls, expecting that a relief expedition would follow. There were great delays in organizing this expedition, from the difficulty of obtaining men, and it was thought that Tippoo-Tip was unfaithful. The men were finally procured, and the expedition left Aruvimi in June, 1888, under command of Major Barttelot. A day or two after they started, Major Barttelot was murdered by one of his private servants. The expedition returned to the Kongo, and was re-organized under Lieut. Jamieson. He was taken ill, and died just as he was ready to start, and no one has been found to take his place; and that relief expedition was abandoned. Reports say that Stanley found the route more difficult than he anticipated; heavy rainfalls, rivers, swamps, and marshes obstructed the way; and that the season was sickly, and a large part of his followers died long before he could have reached Tanganyika.

The reports of his capture, and of his safe return to the Aruvimi River, are known to all. These may or may not be true. Although we have not heard from Stanley for a year and a half, yet it by no means follows that he is dead; for Livingstone, Stanley, and other explorers have been lost for a longer time, and have afterward found their way back to the coast. No man has greater knowledge of the country through which his route lay, or of the character of the natives, or the best manner of dealing with them. Emin Pacha was encamped quietly for nearly two years at Wadelai; and Stanley, in like manner, may have been compelled to remain at some inland point and raise his own provisions.

The Future of Africa.

It is impossible to prophesy the future of any country, much less that of Africa, where the physical features have left so marked an impression upon its inhabitants, and where the animal life is so different from that of the other continents. It is rather by differentiating Africa from other countries that we obtain any data from which to form an opinion of its future.

Africa, as we have seen, is surrounded by a fringe of European settlements. What effect will these settlements have upon Africa? 1st, Will the European population penetrate the interior, and colonize Africa? 2d, Will it subjugate or expel the Africans, or will they fade away like the Indians of our country? 3d, If colonization by Europeans fail, will the African remain the sole inhabitant of the country as barbarian or civilized?

Egypt is now controlled by the English, but its climate is too unhealthy, and its surrounding too unfavorable, for Englishmen; and we may safely assume that their occupation will be temporary, or, if permanent, not as colonists. They will remain, as in India, foreigners and rulers, until the subjugated people rise in their power and expel them, and return to their old life. The English rule, though possibly beneficial to Egypt, is hated by the natives, who demand Egypt for the Egyptians.

Leaving Egypt, we pass an uninhabitable coast, until we come to the French colonies of Algiers. It is nearly sixty years since the French took possession of Algiers. There has been a large emigration from France; but the climate, while excellent as a winter climate for invalids and others, is unfavorable for a permanent habitation, especially for infants. The births in one year have never equalled the deaths. When Algeria was first conquered by the French, it was a wilderness, but is now a garden. The cultivation of the grape has been most successful, and extensive iron-mines have been opened. The French are gradually pushing their way from Algiers across the desert to Timbuctu, and also from Sen-

gambia to Timbuctu. The expense of maintaining the colony has greatly exceeded any revenue derived from it. Though many doubt the political wisdom of retaining it, yet the French have too much pride to acknowledge that the enterprise has been in any way a failure; and they will undoubtedly hold it, and perhaps found an empire. Senegambia and the coast of Guinea, claimed by the French and English, are low and moist, filled with swamps and lagoons, and will prevent any European colonization.

South of the Kongo, the Portuguese claim a wide section of country running across Africa. They have occupied this country over two hundred years. They have done little towards colonizing, and only hold a few trading-posts on the coast and in the interior, dealing principally in slaves, ivory, and gold; and it may well be doubted whether, without holding slaves, they have the stamina or ability to colonize this country, or to produce any permanent impression upon it.

The south portion of Africa, from the 18th parallel on the Atlantic to the 26th parallel on the Indian Ocean, is generally fertile; and the climate is favorable to Europeans, and is capable of sustaining a large population. The growth of Cape Colony has been very slow, but a more rapid growth is anticipated. We believe it will be permanently occupied by the English, who will dispossess the aborigines, and form a great and permanent English state. The coast of Zanzibar, occupied by the Germans and English, is rich and fertile, the climate unhealthy; but when the mountain-ranges are crossed, and the elevated plateaus and lake regions are reached, the interior resembles the Kongo region. Massaua and Suakin, on the Red Sea, are unhealthy and worthless, unless connected by railroad with the upper Nile.

There remains equatorial Africa, including the French settlements on the Ogowe, the region about Lake Chad, the Kongo and its tributaries, and the lake region. The more we learn of equatorial Africa, the greater its natural advantages appear to be. The rivers open up the country in a favorable manner for trade and settlement. Its elevation from 2,000 to 3,000 feet will, I believe, render it healthy, though this elevation is only equal to from ten degrees to fourteen degrees of north latitude. Here all the fruits of the torrid zone, the fruits and most of the grains of the temperate zone, cotton, India-rubber, and sugar-cane, are found.

The country has been unhealthy, a great many Europeans have died, and few have been able to remain more than two or three years without returning to Europe to recuperate. These facts seem to show that the climate is not healthy for Europeans. But, by reason of the exposure incidental to all new settlements, the mortality has been much greater than it will be when the country is settled and the unhealthy stations have been exchanged for healthier localities. Every new country has its peculiar dangers, which must be discovered and understood, then overcome. I believe that these obstacles will be overcome, and that Europeans will occupy all this region, and that it will become a European colony.

If European colonization is successful, European civilization will come into contact with African barbarism. Where such a contest is carried on in a country where the climate is equally favorable to the two races, it can only result in the subjugation or destruction of the inferior race. If the climate is unfavorable to the white population, then, unless the inferior is subjected to the superior, the white population will fail in colonizing the country, and the Negro will either slowly emerge from barbarism, or return to his original degraded condition.

The Negroes have never developed any high degree of civilization; and when they have lived in contact with civilization, and made considerable progress when that contact ceased, they have deteriorated into Barbarism. But, on the other hand, they have never faded away and disappeared, like the Indian of America and the natives of the Southern Archipelago.

Nature has spread a bountiful and never-ending harvest before the Negro, and given to him a climate where neither labor of body or mind, nor clothing, nor a house, is essential to his comfort. All nature invites to an idle life; and it is only through compulsion, and contact with a life from without, that his condition can be improved.

In Africa there is going on a contest between civilization and

barbarism, Christianity and Mohammedanism, freedom and slavery, such as the world has never seen. Who can fail to be interested in the results of this conflict? We know that Africa is capable of the very highest civilization; that it was the birthplace of all civilization. To it we are indebted for the origin of all our arts and sciences, and it possesses to-day the most wonderful works of man. I believe that Africa, whose morning was so bright, and whose night has been so dark, will yet live to see the light of another and higher civilization.

BOOK-REVIEWS.

Hypnotism or Mesmerism. By CHARLES B. CORY. Boston, Mudge. 12°.

COMPARATIVELY little has been done in this country in the study of hypnotism, now occupying so prominent a place in the literatures of France, Germany, and other countries. It is the object of Mr. Cory, who is chairman of the committee on hypnotism, of the American Society for Psychical Research, to inform the American public with reference to those phenomena. Most of the papers here gathered together have been published separately, and the collection forms a very readable introduction into some aspects of the subject. A general paper on hypnotism, partly historical and partly expository, is followed by the most valuable of the papers, in which the factor played by the consent of the subject in the act of hypnotization is ingeniously analyzed. He shows, in one case, that the most intense efforts to will a patient to sleep, when the latter is unaware of the attempt, prove unavailing; while entire passivity is sufficient to cause sleep, when the subject has been led to believe that an attempt to hypnotize her is being made. Mr. Cory sums up his conclusions thus: (1) hypnotism is related to an abnormal constitution of the nervous system; (2) only a small percentage of persons are hypnotizable; (3) the condition is entirely due to suggestion, no one being hypnotizable without being informed, or led to suspect, that he is to be the object of experiment; (4) the condition may be self-induced; (5) in certain cases the hypnotic is insensitive. Mr. Cory's experiments on negative hallucinations are extremely ingenious. He shows, that, when an object is removed by suggestion from the field of vision, the subject takes note of some peculiarity by which to recognize that she is to ignore it. What the eye sees, the mind refuses to recognize. If a number of precisely similar objects are presented, the subject has no longer a clew as to which impression is to be ignored, and the suggestion fails. Mr. Cory has also a talk upon the therapeutic value of hypnotism.

AMONG THE PUBLISHERS.

THE new "Century Dictionary," which has been in course of preparation by The Century Company during the past seven years, is approaching completion, and it is expected that the issue of the work will begin during the coming spring. It will be published by subscription, and in parts, or "sections;" the whole, consisting of about 6,500 pages, to be finally bound into six quarto volumes. Although the printers have been engaged upon the type-setting for more than two years, the publishers have waited until the labor of making the plates is so well advanced that the work can be regularly issued at intervals of about a month, and completed within two years. Probably no work of greater magnitude or importance has been put forth by an American house. The editor-in-chief, Professor William Dwight Whitney of Yale University, who is perhaps the highest authority in philology in both America and England, has been assisted by nearly fifty experts, college professors, and others, each a recognized authority in his own specialty; the design of the dictionary being to make it complete and authoritative in every branch of literature, science, and the arts. It is intended that the botanist shall find in the "Century Dictionary" full definitions of terms in his special line of study; that the civil engineer and the architect can turn to it for the definitions (usually with plans and pictures) of the terms in their own specialties; and so with every other pursuit or profession, — law, music, medicine, chemistry, anatomy, archæology, zoölogy, mineralogy, theology, etc. Each expert is reading the proofs of the entire work; indeed, the

proofs are read by more than sixty people. For seven years not fewer than a hundred persons, and sometimes more, have been working upon this dictionary. Trained readers have been searching the fields of English literature for words, and uses of words, and quotations. Over two thousand authors will be quoted; and it is understood that American books, and even the current literature of the magazines, have been liberally drawn upon. The growth of the English language at the present day is astonishing. It is said that the new "Encyclopædia Britannica" alone furnished ten thousand new words to be defined in the "Century Dictionary." These were generally technical words, which had been coined by the writers of articles in the "Encyclopædia;" but nevertheless they are now born into the language, and are liable to be met with in any one's reading. The new dictionary will contain definitions of probably two hundred thousand words, and these without including any useless compounds. Thousands of quotations, from the vast store which the readers have gathered, will help to illustrate the uses of these words. The work is encyclopedic; that is, encyclopedic in the sense that it gives, in addition to definitions and the etymological history of words, a very great amount of detailed information which has hitherto been found only in the encyclopædias, and often not even in them. There will be about six thousand cuts in the text, the subjects of which have usually been chosen by the experts in charge of the special departments. They have been drawn, whenever possible, from the object itself, and engraved under the supervision of the Art Department of The Century Company. The engravings are said to be of a higher class than have yet found place in any work of this character. It is understood that all rights have been obtained for the issue of this dictionary throughout the English-speaking world, and that it will be published in England simultaneously with its issue in this country.

— Messrs. Longmans, Green, & Co. are about to follow Mr. Besant's "Eulogy of Richard Jefferies" with a volume of Jefferies's uncollected papers, under the apt title of "Field and Hedgerow," in which will appear the latest essays of the Englishman who best continued the tradition of White of Selborne. Among the subjects are "Hours of Spring," "The Makers of Summer," and "Time of Year," which are treated with the sympathy and the knowledge that lead a critic to call Jefferies "the English Thoreau."

— The article on "Walter Scott at Work," by E. H. Woodruff, in the February *Scrivener's*, will contain facsimiles of many interesting pages from the proof-sheets of "Feveril of the Peak," with the pithy criticisms of Ballantyne and replies of Scott on the margin. This literary treasure was purchased in London twenty years ago by Ex-President Andrew D. White of Cornell, who furnishes an introduction to the article. Bishop Potter of New York, in an essay which will appear in the same number, on "Competition in Modern Life," says, "Let us understand, then, that competition—a strife to excel, nay, if you choose, downright rivalry—has a just and rightful place in the plan of any human life. A prize-fight is probably the most disgusting spectacle on earth, but it has in it just one moment which very nearly approaches the sublime; and that is when the combatants shake hands with each other and exchange that salutation as old as the classic arena, 'May the best man win.' It is the equitable thing that the best man should win." George H. Jessop, the playwright, will contribute the story of an Irish outrage, called "The Emergency Men," told from the landlord's point of view. C. D. Gibson, of *Life*, will illustrate it. In an article on "The Physical Development of Women," which Dr. D. A. Sargent of Harvard College will contribute, he says, "At the present time women as a class have more leisure than men for self-improvement, and we must look to them to help on the higher evolution of mind and body, not only in perfecting themselves, but in helping to perfect others. Already three-fourths of the school-teaching force in the United States is composed of women, and they will soon be in the majority as instructors in physical training. The gospel of fresh air and physical improvement is being slowly imbibed by our best families, and the stock of fine specimens of physical womanhood is slowly and steadily improving." W. C. Brownell, whose articles on "French Traits" have received a great deal of discriminating praise, will contribute the last of the group, which discusses

"The Art Instinct." The essays, with several not heretofore printed, will soon be published in book-form. Thomas Sergeant Perry will describe an interesting collection of Græco-Egyptian portraits discovered in 1887 near Fayoum. Professor Ebers believes that some of them were painted three or four centuries before the Christian era. The article is to be fully illustrated from photographs of the originals.

— Messrs. Dodd, Mead, & Co. have issued a catalogue of books, including some of exceeding rarity, such as perfect specimens from the presses of William Caxton, Wynkyn de Worde, and Richard Pynson; a unique copy of the original folio edition of Ben Jonson's works, printed on large paper, with autograph inscription; the original quarto edition of Sidney's "Arcadia;" also the original manuscript of W. H. Ireland's "Shakesperian Forgeries" (numbering 174 lots), together with other desirable rare and choice books. This firm is at all times ready to price, and desirous of purchasing, good books. They are paying special attention to rare books, especially those relating to the early history of America, and would be glad to hear from any one who has books of real value, of which the owner may for any reason wish to dispose.

— Messrs. Cupples & Hurd, Boston, announce for immediate publication "The Eggs of North American Birds," by C. J. Maynard. Such a book has long been needed by students on oölogy, for there is no work upon the subject by any American author which can be called complete. The book begins with the descriptions of the eggs of the water-birds, and the species are numbered as in the "List of the American Ornithologists' Union," the nomenclature being the same so far as it is there given; but every species and subspecies that have been described up to date are included, considerably augmenting that list. All known eggs are described, and the description of each is given so clearly as to render it readily distinguishable. In case of rarities, this is often accomplished by comparison with some well-known species, or with the figured type, of which there are eighty, contained in ten plates, carefully drawn on stone by the author, and accurately colored by hand by Mrs. Maynard. The dimensions of the largest and smallest of a large series of the eggs of each species, number of eggs deposited, nesting-time, breeding-range, and description of nests, are given. At this late day, it is perhaps needless to state that the author has pursued his usual course in preparing the text of the work, and has never used a technical term when a simple one would answer. As a consequence, the descriptions are at once available to all classes of students. The work will be complete in eight parts, each part containing a description of seventy species, more or less, and at least one or two hand-colored plates. The entire work, it is expected, will be completed by the 1st of May, 1889. Sold only by subscription.

— Edward Allen Fay's "Concordance of the Divina Commedia" (Boston, Little, Brown, & Co.) is published under the auspices of the Dante Society, of which James Russell Lowell is president, and Charles Elliott Norton is vice-president. It was reviewed at length in the *Nation* for Oct. 25, 1888. The reviewer closed by saying, "Dr. Fay has put on the titlepage of his book the motto 'In che i gravi labor gli sono agratti.' It well denotes the loving and accurate care with which he has performed his heavy task. His book—the first of its kind in centuries—is not for a day: full generations of lovers and students of Dante will place it on their shelves beside the 'Divina Commedia.'"

— Max O'Rell's book on the United States, which has been awaited with so much eagerness, will be published toward the end of this month by Messrs. Cassell & Co. It will be issued in Paris and London at about the same time. M. Calmann Levy, who publishes the book in France, has already taken advance orders for forty thousand copies; the English outlook is quite as good; and in this country there is every reason to anticipate a sale far exceeding that of England or France. Messrs. Cassell & Co. have paid M. Blouet (Max O'Rell) the largest lump sum that has ever been paid a foreign author for the right of publication in this country. The title of this book is "Jonathan and His Continent; Rambles through American Society," by Max O'Rell and Jack Allyn. The work of translating has been admirably done by Madam Blouet,

who is an English woman and a thorough French scholar. One who has had the privilege of glancing over the proof-sheets of Max O'Rell's book pronounces it the brightest thing he has done, and predicts that it will make a much greater sensation than "John Bull and His Isle," great as was the commotion caused by that clever skit. In giving his impressions of society in the United States, Max O'Rell is often severe, but always kind. He makes a number of statements, however, that are going to call forth contradictions in various quarters, and are likely to stir up some strong criticisms. Each of the great cities that he visited—Philadelphia, Boston, Chicago, etc.—is honored by a special chapter. American women are also so honored, and their beauty is highly complimented; but this will hardly atone in their eyes for the charge brought against them of being badly dressed. Altogether the book is very lively reading, and will unquestionably excite the interest of every American citizen who wants to know what a keen-eyed, intelligent, and witty Frenchman has to say of him and of his country.

—Although the privilege of reprinting in book form the series of papers on "Authors at Home," which appeared in *The Critic*, was requested by a number of publishing-houses, it was the good fortune of Cassell & Co. to secure it. These articles are not mere gossiping sketches. While they are bright and interesting, they have the advantage of authorization as to facts of biography, as each author selected the person to write of him, or gave his approval where the selection was made by the editors. Messrs. Cassell & Co. wish to call attention to the fact that they intend to issue three editions of this book,—a thing unusual in the book-trade. The first will be a regular library edition at \$1.50, while the other two will be "limited" to one hundred copies each. One of these will be an *édition de luxe*, on heavy paper with generous margin, and handsomely bound, while the other will be on large paper especially prepared for "extra illustrating."

—Lee & Shepard will publish at once "Aryas, Semites, and Jews, Jehovah and the Christ," by Lorenzo Burge, author of "Pre-Glacial Man."

—George Routledge & Sons will publish shortly translations of Daudet's "Recollections of a Man of Letters," and Guy de Maupassant's "Sur L'Eau" ("Afloat"). Both volumes will be illustrated.

—Cupples & Hurd have in preparation a new edition of "The Naturalist's Guide," by C. J. Maynard; and also a new work by the same author entitled "Eggs of the Birds of the United States," illustrated by the author, to be issued in monthly parts.

—Charles Scribner's Sons have in press Dr. James McCosh's "First and Fundamental Truths: a Treatise on Metaphysics," which is regarded as the crowning philosophic work of this venerable author's long and fruitful life. They have also in hand a volume of musical essays by Henry T. Fink, the musical critic of the New York *Evening Post*, and author of "Romantic Love and Personal Beauty;" a limited edition of 500 copies of Lester Wallack's "Memories of Fifty Years;" and the Duddleian lecture on "The Validity of Non-Episcopal Ordination," delivered at Harvard University, on Oct. 28 last, by Professor George Park Fisher.

—Macmillan & Co. have in press a new work on Darwinism, by Dr. Alfred Russell Wallace, which promises to have much scientific significance. The first volume in their new English Men of Action Series will be "Gen. Gordon," by Sir William Butler. A volume will be issued each month.

—Harper & Brothers have just ready "A Latin Dictionary for Schools," by Charlton T. Lewis, the editor of "Harper's Latin Dictionary." It is not an abridgment, but an entirely new and independent work, designed to explain every word or phrase in the Latin literature commonly read in schools; viz., the complete works of Cæsar, Terence, Cicero, Livy, Nepos, Vergil, Horace, Ovid, Juvenal, Phædrus, and Curtius, the Catiline and Jugurtha of Sallust, the Germania and Agricola of Tacitus, and a few words found in some extracts of Florus, Eutropius, and Justinus. The original meaning of every word is first given, and then the modifications which it underwent in usage. The editor has preferred illustrations drawn from the earliest authors read by the students,—Cæsar's Gallic War, Cicero's Orations against Catiline, and the first books

of Vergil's *Æneid*. The general plan of the work was not finally adopted until after consultation with thirty of the leading Latin scholars and teachers in the country.

—W. H. Morrison, Washington, D.C., has just published the fourth volume of Mr. James Schouler's "History of the United States under the Constitution." The period covered is 1831-47, and the fifth (and perhaps concluding) volume, which will break off at 1861, is now in active preparation.

—Rénan has completed the second volume of his "History of the Jews." There is one more volume to come.

—Noah Brooks has written an article on the explorer Henry M. Stanley, whose real name he claims is John Rowlands. The article will appear in the February issue of the *St. Nicholas*, and will be illustrated with a new portrait of the explorer, maps, etc.

—The February instalment of the "Lincoln History," in *The Century Magazine*, will contain chapters of peculiar interest, describing (1) the events leading up to the final removal of Gen. McClellan; (2) the financial measures undertaken by Mr. Chase and advocated by Mr. Lincoln for carrying on the war; (3) the relations between President Lincoln and Secretaries Seward and Chase, including the incident of the simultaneous resignation of the two secretaries, and the manner in which Mr. Lincoln averted a political catastrophe.

—The Yankee dialect made famous in Lowell's "Biglow Papers" is now scarcely to be heard in New England, save in odd corners like the home of "Cape Cod Folks," or in the mountain fastnesses in New Hampshire, or among the Berkshire hills. A new writer, Ella Loomis Pratt, who has done some clever sketches from the last-named region in the columns of the *Springfield Republican* and other journals, has treated that life and dialect in a full-fledged novel, "A Gentleman of Fairden," which is announced as a feature of *The Literary News*, New York, for 1889. It is said to abound in pleasant and humorous pictures of places and people in the Berkshires.

—The Open Court Publishing Company, Chicago, have just issued a little pamphlet entitled "Artificial Persons: A Philosophical View of the Law of Corporations," by Charles T. Palmer. The author of this pamphlet is one of the few persons who think that corporations do not have privileges enough. His central thesis is, that a corporation ought to have and exercise all the rights and privileges that belong to a private partnership. He is specially displeased with the rule of law established by the United States Supreme Court, that a corporation chartered by one State cannot exercise corporate privileges in another State unless chartered by that other State also. But his arguments seem to us decidedly weak and inconclusive. A corporation owes its existence to its charter; and its members, in accepting the charter, accept all the conditions and restrictions which that instrument imposes, the chief of which is that they can do nothing but what their charter gives them permission to do. Having accepted these conditions, they have no right afterwards to complain of them. Instead of being a "philosophical view," Mr. Palmer's theory strikes us as both unphilosophical and impolitic.

—The *Family Mail-Bag* is the title of a monthly periodical published at 140 Nassau Street, New York. It is intended for the amusement and instruction of the whole family, and contains an interesting collection of good reading. The January number is the second that has been issued.

—Charles Waldstein's paper on "Ruskin's Work—its Influence upon Modern Life and Thought," will appear in *Harper's Magazine* for February, with a portrait of Ruskin as the frontispiece. In the same number will be printed "A Russian Village—An Artist's Sketch," by Verestchagin.

—Miss Mary F. Seymour's new paper, the *Business Woman's Journal*, which made its first appearance week before last, is devoted to the interests of all women, especially those who work either with brains or hands. It advocates higher education and the adoption of some avocation by every woman whose time is not taken up in household duties, and generally seeks to present the woman's side of every question.

Subscription Agents Wanted.

A favorable arrangement will be made with a responsible person in every community to solicit and to receive subscriptions for the following first-class publications: THE ART INTER CHANGE; THE CHRISTIAN UNION; THE CRITIC; THE FORUM; GOOD HOUSEKEEPING; PUBLIC OPINION; and SCIENCE. This list includes a standard periodical of every class, and they appeal to every taste of educated readers. An agency for these will afford light and profitable employment for responsible persons.

READING CLUBS.—Those who belong to READING CLUBS or contemplate forming them would do well to address us.

For terms address, with references:

THE FORUM PUBLISHING CO.,
253 Fifth Ave., New York.

We cordially endorse this scheme, and will add very liberal commissions for all willing to canvass for *Swiss Cross* subscriptions. N. D. C. Hodges, 47 Lafayette Place, New York.

MAP-MAKING.

All publishers or others desiring to have maps made, either from relief plates or by lithograph, should write to us for estimates before placing their orders elsewhere. Any work entrusted to us will be carefully made under the supervision of our geographical editor, Dr. Franz Boas.

N. D. C. HODGES,

Publisher of *Science*,

"The Week, one of the most valuable papers on the continent."—*Descriptive Review*.

ENLARGED AND IMPROVED.

THE WEEK:

A Canadian Journal of Politics, Literature, Science and Arts.

PUBLISHED EVERY FRIDAY.

\$3.00 per Year. \$1.00 for Four Months.

THE WEEK has entered on its SIXTH year of publication, greatly enlarged and improved in every respect, rendering it still more worthy the cordial support of every one interested in the maintenance of a first-class literary journal.

The independence in politics and criticism which has characterized THE WEEK ever since its first issue will be rigidly maintained; and unceasing efforts will be made to improve its literary character and increase its value and attractiveness as a journal for the cultured home. Many new and able writers are now, or have promised to become, contributors to its columns, and the constant aid of the Publisher will be made to make THE WEEK fully equal to the best literary journals in Britain and the United States.

As heretofore, PROF. GOLDWIN SMITH will, from time to time, contribute articles. London, Paris, Washington and Montreal letters from accomplished correspondents will appear at regular intervals. Special Ottawa Letters will appear during the sessions of Parliament.

THE WEEK in its enlarged form will be the same size as "Harper's Weekly," and the largest paper of its class on the continent.

Insurance.

DELAY IS DANGEROUS.

We call attention to the new form of Accident (indemnity) Insurance policies, which are written by the Merchant's Casualty Insurance Association, 21 Park Row, New York City. John S. Purdy, Secretary. These policies cover weekly allowances of from \$10 to \$25, according to occupation, at a cost of only \$6 a year exclusive of the cost to join, which is \$5 payable once only. The public, as a rule, carry life insurance, and the ordinary accident policies issued by companies, paying a sum in case of death, is not so desirable as one of these indemnity policies in case of accidents, which are so plentiful in this fast age with its railroad horrors, fast driving, electric wires and other countless forms of danger to which the public is constantly exposed. The fact of the Association having no unpaid claims, and its having just passed an examination by the Insurance Department of New York State, shows that the management is liberal with its policy-holders and conservative in its action. The Association also desires to secure energetic Agents in every village and town, to whom territory and favorable terms will be given.

THE SECRET DOCTRINE.

The Synthesis of Science, Religion and Philosophy.

BY H. P. BLAVATSKY,

Author of "ISIS UNVEILED," and founder of the Theosophical Society.

2 Vols. Royal Octavo. Cloth \$10.00.

AN UNPRECEDENTED LITERARY EVENT.

This book is written with the especial aim: "to show that Nature is not a 'fortuitous concourse of atoms,' and to assign to man his rightful place in the scheme of the Universe . . . to show that the occult side of nature has never been approached by the science of civilization." It is based upon stanzas from the **BOOK OF DZYAN**, an archaic MSS. unknown to the Western world, with erudite commentaries, explanations and elaborations. In the Addenda Modern Science is contrasted with Esoteric Science.

The **Darwinian theory of Evolution** is shown to be wrong, and it is asserted by the author that the Apes are not our ancestors but are degenerate descendants of prehistoric man.

The book also attempts to show that all the forms upon the earth have been produced by man who has passed through each one in his evolution.

The **Moon** is held to be the progenitor of the Earth and not a mass that was thrown off by the latter in cooling.

The author shows enormous erudition, and if readers call the book an invention they must place the writer at the head of the geniuses of the age.

CHARLES T. DILLINGHAM, 718-720 Broadway, New York.

GUARANTY INVESTMENT COMPANY

CAPITAL \$250,000.

Hon. ALBERT H. HORTON (Chief Justice, Kansas Supreme Court), Topeka, Kan., Pres't.

7% Guaranteed Farm Mortgages 7%

The Company calls the special attention of Investors to the following points :

- I. All loans guaranteed and interest payable semi-annually at the Importers' & Traders' National Bank, New York.
- II. Unusual fulness of information, not only about the security itself, but about the general development of the section where the farm is located.
- III. An examination each year of the general business of the Company and the Mortgages themselves by a COMMITTEE OF INVESTORS sent for the purpose.
- IV. Many hundred Mortgages taken and NOT A SINGLE FORECLOSURE.
- V. Exhibitions in New York at frequent intervals, of Kansas and Nebraska Farm Products. The Exhibition at the American Institute in the fall of 1888, received the *HIGHEST AWARD* of superiority.
- VI. Monthly Bulletins giving full information about all Mortgages offered for sale.

Address for Monthly Bulletin and Investors' Committee Report for 1888,

FOOD ADULTERATION

And its Detection. With photomicrographic plates and a bibliographical appendix. By J. P. Battershall. 328 pages, 8vo, cloth. Price, \$3.50. Circulars and Catalogues on application. E. & F. N. SPON, 12 Cortlandt St., New York.

WHY YOU SHOULD USE

Scott's Emulsion

OF **Cod Liver Oil** WITH
HYPOPHOSPHITES.

It is used and endorsed by Physicians because it is the best.

It is Palatable as Milk.

It is three times as efficacious as plain Cod Liver Oil.

It is far superior to all other so-called Emulsions.

It is a perfect Emulsion, does not separate or change.

It is wonderful as a flesh producer.

It is the best remedy for Consumption, Scrofula, Bronchitis, Wasting Diseases, Chronic Coughs and Colds.

Sold by all Druggists.

SCOTT & BOWNE, Chemists, N.Y.

SCIENCE

FRIDAY, JANUARY 25, 1889.

THE STORAGE OF ELECTRICITY.

ONE of the greatest drawbacks to the introduction of electricity as a servant of man has heretofore been a method of providing a suitable means of accumulating it, so as to have it at hand when and where wanted. The development of storage-batteries is doing as much to-day to advance the universal adoption of electricity as the dynamo when invented did to introduce it.

To Gaston Planté, more than to any other investigator, are we indebted for our knowledge of storage-batteries. He it was who

above, the plates of metallic lead become gradually converted into spongy lead on the negative pole, and peroxide of lead on the positive pole, and that such a cell would hold current and deliver it again with but small loss. The chief reason that a storage-battery of this character could not be made of use practically, was the fact that to form the lead plates it was necessary to pass the charging current daily back and forth by a series of reversals for many months before they became converted to their new forms.

On the discovery and perfecting of the mechanical production of electricity by means of the dynamo, the production of a suitable form of storage immediately became one of the leading questions of the day; but how this formation of Planté's plates might be has-

JULIEN STORAGE-BATTERY EXHIBIT AT THE AMERICAN INSTITUTE FAIR.

first took advantage of secondary currents in voltaic batteries. He examined the entire problem of the polarization of electrodes, using all kinds of metals as electrodes or plates, and many different liquids as electrolytes; but he found that the greatest efficiency was produced by electrodes of lead in diluted sulphuric acid.

The first set of Planté cells was exhibited in 1860, before the Paris Academy of Sciences. It was immediately recognized that the storage-battery had a field peculiarly its own, and that its application was only limited by the application of electricity. This was all before the introduction of the dynamo; and at that time little real commercial value was attached to the discovery, as the accumulators had to be charged by means of primary batteries, and it was then well known that electricity, when produced by chemical means, was far too expensive for any purpose outside of the laboratory.

Mr. Planté's discovery consisted of the fact, that, if a current of electricity be passed back and forth through a pile composed as

tened, so as to reduce the cost of manufacture within practical limits, was what was first to be solved. The first step forward was the artificial application of the oxides found on Planté's plates to sheets of lead which were bound on by strips of felt. After a short time, however, under the action of the sulphuric acid, these strips of felt became eaten, and the surface of the plates fell away.

It remained for Mr. Edmond Julien, a Belgian engineer, to make a battery of such a form as to be electrically and mechanically suited to the requirements. His battery consists of perforated plates or grids, into which are pressed the active materials or oxides, which, after a short charge, become almost one homogeneous mass, being what Planté in a crude way produced by the continuous action of a series of reversals of a current. This, however important, did not turn out to be his most valuable invention. When put to practical use, it was found that after a short time the positive plates showed signs of corrosion, which limited their life to about one year. He therefore entered upon the work of construct-

ing a battery free from its defects, and, after a period of six years of continuous experimenting, he produced the Julien battery in its present form (represented in the accompanying cut), founded upon the principle of an inoxidizable support plate, which is materially opposed to that employed by his predecessors. All support plates made before Mr. Julien's discovery were founded on the principle of the oxidization of the positive plates or their conversion into peroxide, so that they soon fell to pieces.

The difference between a lead plate and one composed of this inoxidizable alloy—lead, antimony, and mercury—is perfectly evident: one is practically useless, while the other can be successfully used for years. The importance of this point is made plain by a recent decision of the commissioner of patents.

The following is an extract from the report of Benton J. Hall, commissioner, Dec. 8, 1888, in the case of an interference between John S. Sellon, assignor to the Electrical Accumulator Company, and Edmond Julien:—

"The addition of mercury as a battery constituent is of great value in the formation of support plates of secondary batteries, on account of its tendency to unite with the other metal or metals of the plate, forming a more active union or contact between the plate which contains an admixture of mercury, and thus diminishing the resistance of the electrode, and therefore the resistance of the whole battery, thereby increasing the current, which is a result of the greatest importance in the use and application of secondary batteries.

"This property (that of diminishing the resistance of the electrodes) is so valuable, that, in the manufacture of plates for contact batteries, the addition of mercury to alloys of lead and antimony gives marked advantages over batteries formed of lead and antimony alone, and renders them preferred for secondary-battery purposes. This is the characteristic value of the Julien battery, or the triple alloy battery of Julien, which is so much preferred in modern use on account of its durability and efficiency.

"The action of mercury in the three-element battery—that of Julien—should at once remove it from comparison with two-metal batteries of any kind as yet known, and which appears to be due to the admixture of mercury in the alloy, which renders it unlike the other batteries with which it is classified wrongly in this interference, and with which it should not have been placed in interference; for the presence of mercury in the plate gives it a distinct and separate place, and forms a different alloy."

These plates, in addition to being inoxidizable, and thus having practically an unlimited life, are of great rigidity and mechanical durability, which enables them to be made very much lighter, and also prevents any tendency of bending, or, as it is called, "buckling," under the severe strain of heavy rates of charge and discharge.

To illustrate the difference in weight between a battery whose plates are made of pure lead and of Mr. Julien's compound, I quote from pamphlets issued by companies engaged in the manufacture of these batteries:—

	Weight of Cell in Pounds.	Capacity in Ampère Hours.	Capacity per Pound.
Gibson (lead).....	120	200	1.6
Faure (lead).....	121	300	2.5
Julien (alloy).....	32	150	4.7

The value of Mr. Julien's inventions was immediately recognized by capitalists in America, which resulted in the organization of the Julien Electric Company, to exploit his systems of traction and lighting by means of these batteries. To that company is due the great progress which has been made within the last two years in the storage-battery industry. American ingenuity and proclivity for labor-saving machinery has grappled with and overcome almost all the difficulties in the manufacture of these batteries, which, up to a short time ago, had been considered insurmountable.

The plates were at first cast, pasted, and pressed entirely by hand, and, in fact, these crude methods are still in use in Europe

and by all other makers in this country; but the Julien Company have a machine capable of producing in one day one thousand completely finished plates. It is almost automatic in its action, and requires but one attendant. All the plates are uniform, and the action of the battery is therefore free from the irregularities inseparable from hand-made batteries.

A word as to the application of storage-batteries. They have been extensively and successfully used for the following purposes: electric lighting of buildings of every description; lighting of railway-trains, street-cars, and omnibuses; the traction of all vehicles, more especially street-cars; the propulsion of yachts, launches, and pleasure-boats; the lighting of steam-vessels, etc.; running motors of all kinds; telegraphy, signalling, etc.; medical uses; electroplating; general laboratory-work, etc.

Electric lighting, however, is one of its most interesting and useful applications. It is here that its functions as a reservoir of energy become utilized to the greatest advantage.

Where lights are supplied direct from a dynamo, the machinery must have a power-capacity equal to the maximum number of lamps in a given installation; and, since the lights are usually only needed a few hours out of each twenty-four, the plant will remain idle the rest of the time. Moreover, to secure first-class results, the engine and dynamo must be of the best construction and design, steady and quick regulating, to prevent flickering. But with storage-batteries the generator is not limited as to the time or manner of working, but can prepare its supply slowly, ahead of time, during the day, in the many hours at its disposal; and, in addition to its requiring a dynamo of very much smaller size, the machinery may be of much simpler and cheaper construction, as with the battery irregularities in movement can exist without in any way affecting the quality of the light, since the current given off from the accumulators is always uniform and regular, even while the charging current is subject to marked fluctuations. The storage-battery is, in fact, an equalizer and regulator to the dynamo, besides acting as a reservoir in case of accident, which is liable to happen with the best machinery.

In all cases a direct lighting-plant can be made complete and perfectly reliable by the addition of storage-batteries, as the surplus energy, which can be stored while the dynamo is running under light load, can be utilized during the remaining hours of the day or night.

With water we cannot expect a reliable supply without providing suitable facilities for accumulating and storing certain quantities of it; and in every case we have such means of storage, whether it be a reservoir, tank, cistern, or well. With gas the supply must be yet more uncertain and unreliable without the gasometer, in which the product of the retorts can be stored ahead of the time of consumption. In the profitable and practical application of electricity we must also have a means of storing to insure an absolutely steady and uniform current, so necessary with incandescent lighting, and also to provide against any possibility of the extinguishing of the lights by failure of the generating-plant.

Another great advantage to be obtained from the use of storage-batteries is the great increase in the life of the lamps, due to the fact that the current flows with absolute steadiness at all times, thus adding from twenty-five to fifty per cent to their life, and effecting a great saving, for the renewal of lamps is one of the chief items of expense in the maintenance of an installation.

They can, for example, be charged without trouble and danger from an arc as well as incandescent circuit. Thus the electric light may be introduced in many places where a special generating-plant for charging batteries could not be employed, or where its expense would be objectionable. This permits of the introduction of incandescent lighting without too great initial cost of installation, or in the subsequent running expense.

In places where an arc circuit is already installed, the introduction of the incandescent light becomes a comparatively simple and inexpensive matter. The arc dynamo can be used in the day-time to charge the batteries, and at night to supply the arc lamps, while the stored electrical energy is used to supply incandescent lamps.

What one generation looks upon as a luxury the next regards as a necessity. Of the numerous applications of the inventions utilized during the present century for the promotion and extension of

the comforts and luxuries of life, there has been, perhaps, nothing more wonderful than the improvements in the methods of obtaining and utilizing light.

As lately as fifty years ago the candle was the chief illuminant in use. This was replaced by the oil-lamp, which was undoubtedly a great step in the way of progress. A little later this luxury made way for gaslight. But progress could not stop here. Having been educated to a proper appreciation of good light, the public, not satisfied with this improvement, demands that gas, in turn, shall make room for some other agent. The electric light has proved itself the only agency for the accomplishment of the difficulty of still further improvement.

Among its manifold advantages are,—

The great superiority and steadiness of the light.

It does not over-heat the atmosphere, nor charge it with poisonous gases, while depriving the air of its life-sustaining element, oxygen.

It also removes all danger to life and health caused by the escape of gas.

Ventilation, a matter of such vital importance to health and life, thus becomes a comparatively simple matter, the difficulties in this direction no longer increasing in inverse ratio to the amount of light used, as with gas.

The safety it offers over every other form of light, removing the ever-present danger of fire, by doing away entirely with the use of the match. By simply touching a button or turning a switch, any designated light or all the lights in a house can be lit from any part of the building. They also admit of a much more advantageous distribution of light.

The cost of insurance where electric light is used is in all cases reduced.

Its freedom from smoke and deleterious gases, which work such incalculable destruction to ceilings, walls, decorations, books, paintings, etc., makes its adoption the greatest possible saving. But, great as has been its success, its introduction into general use has been limited, as it has not been placed within the reach of all. It has been shut out from the very place where good light is most needed and appreciated, "at home," owing entirely to the method of producing it,—that of lighting direct from a dynamo.

The electric lighting of houses distant from a central lighting-station has heretofore, to a certain extent, been an impossibility, owing chiefly to the fact that a steam-plant has been necessary, and that in the production of electric light direct from a dynamo it has been impossible to obtain light except when the dynamo is running.

The operation of a steam-engine necessitates the presence of an experienced engineer, which immediately makes its production so expensive as to be beyond the reach of any but the more wealthy.

The time when light is most required in a private house is between the hours of six and ten or twelve o'clock at night, when it is almost impossible to obtain the services of a competent engineer.

The noises and vibrations attending the operation of a steam-engine have been another drawback to its introduction, for few are willing to have machinery in operation in a private house until after the hour of midnight or during the time when light is required.

There has been no means of producing electric light with the direct lighting method so that light may be available at all times except by the running of a dynamo continuously, and, unless light can be available at all times, it fails to compete with gas.

The storage-battery, however, seems to overcome all these difficulties, and to solve the problem of incandescent lighting in isolated cases.

In the course of some remarks recently made before an electric-light association by a prominent New York electrical engineer, the importance of storage-batteries in electric lighting was very clearly shown in the following: "I would call the attention of the members, for instance, to the lighting of private residences which are detached, country residences, summer residences, and large mansions. I believe that here the storage-battery has a sphere which it will hold as its own, for the reason that the direct system of lighting of to-day does not afford all the requisites of a perfect application of electricity for lighting. It has not supplanted gas, and you will find

that wherever isolated plants are in use to-day they still have gas. Now, I do not consider that we can look upon isolated lighting as a success until we see it drive gas out altogether. To do that, we must have electricity 'on tap' for twenty-four hours a day, the same as gas, and I can conceive of no system by which this can be done successfully except one involving the use of storage-batteries as an accessory, if nothing more."

A storage-battery can be charged with the use of almost any form of power during the hours of the day, and in many instances energy now running to waste may be utilized in laying up a supply for night use.

One of the interesting developments in this connection is the prominence of the gas-engine as a producer of electric light. This power seems to be particularly fitted for work in connection with storage-batteries. The operation of these engines is so simple that they can be cared for and run by the employees of almost any house. The power is always available. The gas in the engine is ignited by a spark from the battery, and, in fact, can be started by simply turning a battery switch, using the dynamo for a moment

THE JULIEN STORAGE-BATTERY.

as a motor to bring the engine up to speed. Thus by the simple operating of a switch the entire plant is set in motion. The battery is charged during the day, and at night, when the engine is shut down, enough energy will have been stored to supply the house with light for the entire night.

The accompanying illustration represents one of the most interesting displays at the American Institute Fair this season, the installation of the Julien Electric Company, showing the application of storage-batteries to the lighting of private residences in connection with a Baldwin gas-engine and a United States dynamo. The plant consisted of a 4-horse-power gas-engine coupled to a 30-light dynamo and 36 cells of Julien battery. There were in the exhibit some 95 16-candle-power lamps, in addition to two $\frac{1}{2}$ -horse-power electric motors used for operating a fan and sewing-machine,—another application to family needs. The current from the battery can also be used for pumping water, the running of electric bells, burglar alarms, and other light work. The dynamo charges the battery during the day; and at night, when the full number of lights is turned on, the dynamo takes care of 30 lights, and the remaining 65 are taken from the accumulators. It will thus be seen, that, in addition to serving as a reservoir to be called on when the plant is not in operation, by the running of the dynamo, and at the same time discharging from the battery, a largely increased number of lamps is available, thus reducing very considerably the amount of power necessary to be introduced. It is generally acknowledged that light derived from storage-batteries is of greater steadiness than that produced direct, thus increasing considerably the life of the lamps.

The cell employed was the type 19 C of the Julien Company, weighing complete about 44 pounds, which is rated by that company as having a capacity of 200 ampère-hours, and the rate of discharge given is 30 ampères. It will be seen, however, that, as these lamps take about $\frac{1}{3}$ of an ampère each, the batteries were being discharged at about twice their normal rate, and, where occasion required, the engine was stopped and the batteries supplied current for the entire plant, thus discharging at almost three times their nominal rate.

This is a particularly creditable showing for these batteries. The principal difficulty heretofore in the use of accumulators has been that they have not been permitted to be discharged at a greater rate than from about one-tenth to one-eighth of their capacity, whereas in this exhibit they were regularly required to deliver their full capacity in about four hours.

The cells were in use from the commencement of the exhibition, the 1st of October, until Dec. 15, and did not in that time require the least attention on the part of the company, the plant being run entirely by a man in charge of the gas-engines, who, until the opening of the fair, had never been in charge of an accumulator plant.

The lights were burned four hours each night, which, discharging at the rate of about 60 ampères, and occasionally at 80 to 85, made a total of 250 ampère hours taken out, while the rated capacity (discharging at the nominal rate) is but 200 ampère hours. This is an indication of the large amount of reserve energy there is always on hand in case of an accident or stoppage of the generating-plant, or in case of an emergency.

A BLIZZARD MEETS AN ELECTRIC ROAD.

RECENTLY one of the severest tests to which an electric railroad can be subjected was experienced by the Davenport Electric Line, installed by the Sprague Electric Railway and Motor Company of New York, at Davenport, Io., and one which proves most conclusively that an electric railway can be operated even under the most adverse conditions of weather. The blizzard, which had been howling about the Dakota prairies during the first part of the week, and getting up its strength by snowing in the territory farmers, decided to come south, and on Jan. 9 struck the city of Davenport.

The snow, which was of the heavy damp variety, fell all day, and covered the streets to the depth of from four or five inches to one foot on a level, and in several places caused deep drifts over the line of the electric railway. In spite of this, the cars on the electric line kept running uninterruptedly, carrying a large number of passengers, and proving conclusively that no amount of snow could prevent the cars from running on schedule time. The president of the road, Mr. W. L. Allen, was greatly pleased with the signal triumph of the Sprague people, who had told him in the autumn that snow could not interfere with the operation of the road, and is enthusiastic over electric railways.

This road has been in operation about four months, and has been giving very great satisfaction to the management and citizens of Davenport, who have had a much better service since its installation than they ever had while the road was being operated by horses. The cars move faster, are under quicker and more perfect control, and are much more easily managed than the cars drawn by animal power. The regular Sprague overhead system, with small No. 6 silicon-bronze wire as a working conductor, is in use upon this road. All the latest devices and improvements adopted by the Sprague Company for facilitating the operation and increasing the convenience of their electric roads are in use here.

Among the principal points of excellence of the Sprague system of electric railway, may be mentioned the system of conducting current to the cars by means of a working conductor, separate from the main conductor, but connected to it at intervals by automatic cut-outs, by which an accident on any portion of the line does not interfere with the remainder of the road; the use of flexible suspension for the motors, preventing accident from sudden strain; and the method of controlling the motors from either platform without the use of idle resistance.

TESTING A PNEUMATIC DYNAMITE GUN.

ON Saturday last a test was made of the capabilities of a pneumatic gun of fifteen inches bore, forty feet in length, intended to throw a shell containing 700 pounds of dynamite and nitro-gelatin. Two shots were fired, when, owing to the leakage of an air-valve, the experiments were postponed to some future time. As far as the trial went, the results were satisfactory. A mile from the gun, which was located at Fort Lafayette, in the Narrows, New York Bay, a rectangular space 50 by 100 feet was marked off in the waters of Gravesend Bay by four buoys. The first projectile from the gun passed about 250 yards beyond the target, though it was an excellent line shot. Its course was easily followed by the unaided eye from the moment it left the gun until it entered the water. It passed through the air as though shot from a rifled gun, without an oscillation or a "wobble." It exploded a moment after striking the surface, throwing up the water, like an immense fountain, from 100 to 200 feet into the air. This first projectile contained 170 pounds of dynamite.

The second projectile, containing 200 pounds of dynamite and 300 pounds of nitro-gelatin, a larger charge than had ever been used before, fell short of the mark, but the effects of its explosion were tremendous. A reversed Niagara, of water, mud, and stones, shot perhaps 200 feet into the air. It seemed as though a water-volcano had broken forth in Gravesend Bay.

The reason for this shell not reaching the target appeared to be that there was some defect in the tail-piece, which is depended upon to keep it from oscillating or wobbling in its flight. Some part of this tail-piece was evidently injured in leaving the gun, and the consequence was that the longitudinal axis of the projectile (which was six or seven feet in length) deviated from the line of flight. It swung through an angle of about forty degrees, back and forth, while describing the arc of flight, the oscillation decreasing as the projectile approached the water.

Further tests of the gun are promised in the near future, and they will be watched with interest, as the dynamite gun is destined to take an important place in the warfare of the future.

THE RISLEY AND LAKE COMPOSING-MACHINE.

THERE is now on exhibition at No. 22 Spruce Street, this city, a machine intended to dispense with the use of type in certain kinds of printing. It is the invention of Messrs. Risley and Lake; and though only an experimental machine, and therefore somewhat imperfect in many of its details, it does its work speedily and well. The printing done by it is not as perfect or as pleasing to the eye as ordinary letterpress work, but is good enough to satisfy the requirements of that important branch of the printer's art known as law printing, in which small editions of lawyers' briefs, legal arguments, evidence, etc., are desired in a few hours' time.

This machine, in its present crude but very promising stage of development, is shown in the accompanying illustration. As a satisfactory description of it cannot be given unless the machine be seen in operation, only a few of its features will be touched upon here. Though not so complicated as the engraving makes it appear, still many of the mechanical movements involved are so novel that they must be seen before they can be readily understood.

It will be perceived that there is a key-board like that of an ordinary type-writer, the use of which is obvious. There is a key for each character used. These characters are all cast or cut on one cylindrical shell or sleeve, in which feature the machine resembles the well-known Crandall type-writer. This type-shell may be seen, in the illustration, at the centre of the machine, immediately to the rear of the key-board, and in front of the sheet of paper upon which the printing is to be done. One peculiar feature of this machine is, that the printing does not begin until the keys for about fifty characters have been struck, so that the operator is always at least a line ahead of the impressions as they appear on the paper. The keys, instead of acting directly upon the printing apparatus, act upon a set of pins, which are carried in a revolving disk; each key, when depressed, setting its appropriate pin in position for actuating the printing mechanism when the disk shall have carried it around to the proper point. In this way there are always stored

up, as it were, ready for use, fifty or more characters, and these are made to appear upon the paper, in proper place and order, by the automatic action of the machine, even after the operator ceases work at the key-board.

A unique feature of the invention is that by which the lines are "justified;" that is, lengthened or shortened to conform to the width of the column or page. To do this, when movable types are used, as in ordinary type-setting, the compositor, when the line is nearly completed, puts thicker or thinner spaces between the words. Otherwise the lines would be unequal in length, presenting a ragged appearance, similar to that of type-written work. By an ingenious device upon this machine, when a sufficient number of words to approximately fill a line have been registered or "pinned" upon the revolving disk, the justifying or spacing between the words is done automatically; and when the words subsequently appear upon the paper, they fill the line as accurately as do the words in

city, who are now erecting extensive workshops for its manufacture. The chief moving spirit in the enterprise of bringing it to the front and putting it upon a commercial basis is Mr. Edward F. Underhill, official stenographer of the New York Surrogate's Court, who has had it in use in his office for several months, with highly satisfactory results.

METHYLATED ALCOHOL.¹

THE employment of alcohol so adulterated as to render it unfit for use as a beverage, free of tax, in the arts and manufactures, has lately been receiving attention by Congress. To prevent fraud on the revenue, the degree of adulteration that would be permitted should be governed by two considerations,—first, the minimum amount of adulterant that should be added to make the subsequent purification of the alcohol unprofitable; and, second, the maximum

RISLEY AND LAKE COMPOSING-MACHINE.

this line, and the spacing between the words is as even as it could be made by the most expert compositor. In fact, the spacing is, and must of necessity be, mathematically correct.

The reproduction of the work done on the machine now on exhibition is accomplished by lithography. The printing by the machine is done with lithographic ink on paper specially prepared. The impression is then transferred to stone in the usual manner, and the desired number of copies struck off. The first printing or composing on the machine is done in less than a fourth of the time required when movable types are used, the ordinary speed being from twenty to twenty-five words a minute. The cost of transferring to stone is said to be less than the "making up" of forms for the press in ordinary printing, and there is no "distribution" of type.

This machine has also been tested with a view to making matrices for the casting of stereotype plates, but the experiments have not been carried sufficiently far, as yet, to determine what may be accomplished by it in that direction. The patents covering the machine are controlled by the Graphic Process Company of this

amount of adulterant that can be added without rendering the use of such adulterated alcohol unsuitable in the arts and manufactures.

Compounds known as methylated spirits, made by adulterating pure grain spirits, free of tax, with wood naphtha (methyl alcohol), are more expensive than such pure spirits, because the adulterant is, contrary to what is usual in such cases, more costly than the article adulterated.

For most manufacturing purposes, the addition of any amount of adulterant to grain alcohol must be regarded as just so much added useless matter. Besides, there is no purpose for which methylated spirits is used where the employment of grain alcohol would not yield both a cleaner and better product; in addition, there are many cases in which methylated spirits cannot be used at all.

Let us see what has been done in this matter in England and Germany, where laws and regulations on the subject have been enacted.

¹ Paper read before the Chemical Society of Washington, Jan. 10, 1889, by Edgar Richards.

Great Britain.

In England, according to the definition of their regulations and law, "the spirits must be plain spirits or unsweetened foreign spirits, of not less strength than 50 per cent over proof, or rum of not less strength than 20 per cent over proof, and must be mixed with at least one-ninth of their bulk of wood naphtha. This mixture is termed 'methylated spirits.'" Accordingly, 10 per cent is the amount of added impurity.

The Board of Inland Revenue only permits the use of a decidedly impure and crude wood naphtha for this purpose, of a not "less strength than 60 over proof," and which must not be used until a sample has been submitted and approved by the chemical department of Somerset House. Until the necessary approval has been obtained, the naphtha is kept under official lock and key, and only allowed to be used for mixing under certain regulations; and the whole quantity, 100 gallons, "must be drawn off and used before any other naphtha is conveyed into the vat." "Naphtha disapproved by the board must be immediately removed from the naphtha warehouse."

The mixing must be done in the presence of officers of inland revenue, and "500 gallons of methylated spirits is the least quantity which may be prepared at one time in a mixing-room, whether the spirits used be British or foreign spirits." "The mixing must take place in a vat of sufficient capacity to admit of the spirits and naphtha being thoroughly mixed."

Methylated spirits is "supplied to such persons only as undertake to use it in the arts and manufactures, subject to the board's approval," and on entering into bond in the sum of from £200 to £1,000 penalty, depending on the annual consumption which they propose to employ. Scientific societies and hospitals who obtain the methylated spirits for scientific purposes are not required to give a bond.

All persons authorized to use methylated spirits are warned that they are not at liberty to purify the spirits in any manner whatever. "No person can legally use methylated spirits, or any derivative thereof, in the manufacture, composition, or preparation of any article whatever capable of being used either wholly or partially as a beverage, or internally as a medicine." It may be used, however, "in the preparation of sulphuric ether, chloroform, hydrate of chloral, soap, compound camphor, aconite, and belladonna liniments," without coming under the foregoing prohibition.

The premises of all users of methylated spirits are liable to inspection of the inland revenue officers at all times.

The following table gives the total quantity of methylated spirits produced in Great Britain since 1881, taken from the annual reports of the commissioners of her Majesty's inland revenue:—

Methylated Spirits.

1881.....	1,762,559	gallons.
1882.....	1,991,765	"
1883.....	2,100,765	"
1884.....	2,236,962	"
1885.....	2,334,935	"
1886.....	2,477,798	"
1887.....	2,673,375	"
1888.....	2,757,402	"

This table shows a steadily increasing consumption.

Canada.

In Canada, where a similar law to England was for many years in force, the government permitted methylated alcohol to be manufactured in bond for use in the arts, and to be withdrawn upon the payment of an excise-tax of fifteen cents per gallon. Twelve gallons of wood naphtha of not less than 60 per cent over proof were added to 100 gallons of grain alcohol. Subsequently the Inland Revenue Department ascertained that such spirits were being demethylated and rendered potable, thus causing a serious loss of revenue. The law was therefore repealed, and the Department of Inland Revenue undertook to supply the trade with a substitute, composed of 25 per cent of wood naphtha and 75 per cent grain alcohol, which is supplied only to varnish-makers and other persons engaged in the mechanical arts. The persons using this grade of methylated spirits give bonds, in the sum of \$2,000, that such spirits

shall be used solely for the purposes mentioned, and in the premises described in their application. An inferior grade, consisting of equal parts of wood naphtha and grain alcohol, is supplied the trade without any restrictions as to its use (see letter from Assistant Commissioner W. J. Gerald, of Oct. 25, 1888, published in the "Annual Report of the Commissioners of Internal Revenue, 1888," p. cxx.).

Germany.

The German spirit law, and the regulations issued to carry it into effect, permit of a sliding scale of adulteration, depending on the designated use of the "denaturised spirits."

For most purposes, a mixture of two parts of wood naphtha and one part pyridine bases to one hundred parts of alcohol is permitted. The wood naphtha is submitted to certain prescribed tests in regard to color, specific gravity, boiling-point, miscibility with water, contents of acetone, and capacity for absorbing bromine. The pyridine bases are likewise examined for color, behavior towards cadmium chloride, boiling-point, miscibility with water, contents of water, and volatility.

The regulations that have been issued from time to time have variously amended those preceding them. Those of June 21, 1888, are the latest, and several of the provisions contained therein did not come into force till the first of this year.

Makers of the general denaturising agent are permitted to add "40 grams of oil of lavender or 60 grams of oil of rosemary to every litre." Such addition has likewise to reach a prescribed standard.

"It is illegal to remove, or partially remove, the denaturation agent, or to add substances whereby the taste or smell of the denaturised spirits is altered." The selling or placing on sale of such purified spirits is likewise declared illegal.

Manufacturers may also use "five parts of wood naphtha instead of the general denaturation agent or pyridine bases" under certain regulations, and may sell the same "to persons engaged in industrial pursuits."

Varnish and polish makers may use "0.5 per cent of oil of turpentine" for this purpose, and may likewise sell varnishes and polishes so prepared to the trade. In "the manufacture of glazes for brewers' use the denaturation may be made with 20 per cent of a solution of one part of shellac in two parts of 95-per-cent alcohol. The alcohol used for such solution is to be free of tax."

In "the preparation of the alkaloids, medicinal extracts, chloroform, iodoform, chloral hydrate, sulphuric ether, acetic ether for technical purposes, collodion, tannin, salicylic acid and its salts, white lead and acetates, the alcohol may be denaturised by 0.5 per cent of oil of turpentine, or by 0.025 per cent of animal oil, or 10 per cent sulphuric ether."

"For making colored varnishes, 0.5 per cent of oil of turpentine, or 0.025 per cent of animal oil," is permitted; and for alcohol used in the "analysis of sugar-beets in sugar-factories, 0.025 per cent of animal oil" is the quantity prescribed for denaturation.

"For the preparation of acetic ether intended for technical purposes, freedom from tax can only be granted for the alcohol to be used under condition that besides the prescribed denaturation of the alcohol," as already mentioned, the ultimate destination of the acetic ether must be indicated, and will be controlled by suitable regulations.

The "animal oil, oil of turpentine, sulphuric ether, and shellac solutions intended to be used as denaturation agents, must satisfy the prescribed tests," and be submitted to an officially appointed chemist, and be approved by him before they are permitted to be used for the purpose. The expense of such test is borne by the manufacturer.

"For the preparation of vinegar, alcohol may be denaturised by 200 per cent of acetic acid of 3 per cent, or by 30 per cent of acetic acid (vinegar) of 6 per cent, or by 70 per cent water and 100 per cent beer." It is also allowable to use, "besides the prescribed quantity of acetic acid (vinegar), 100 per cent of pure genuine wine instead of the beer and water."

Alcohol of "less than 80 per cent" is not permitted to be treated, and "not less than 50 litres" must be treated at a time. The mixing must take place under the supervision of two revenue officers.

United States.

The bill now before Congress contemplates: 1. The use of large, bonded warehouses for the storing exclusively of spirits "of not less than 180 per cent proof." 2. The removal of such spirits free of tax from the bonded alcohol warehouses to bonded storerooms, to be "used in manufacturing establishments, in the industrial arts, and in the manufacture of articles, preparations, compounds, acetic and other acids, and medicinal drugs or chemicals." "The manufacture of tinctures, proprietary articles, wines, liquors, cordials, bitters, or other alcoholic compounds which are used or sold as beverages," is excluded from the provisions of the act. "The commissioner of internal revenue, with the approval of the secretary of the treasury," is to make and enforce all needful regulations. The bonds for the alcohol warehouses are not to be in a less sum "than \$100,000;" and those for storerooms to be not "less than \$5,000;" all operations conducted in such bonded establishments to be under the supervision of revenue officers, as is now customary in all distillery warehouses. 3. The proprietor of any bonded alcohol warehouse may methylate such spirits free of tax, so as to cause them "to be unfit for use as a beverage," under prescribed proportions and regulations; and such methylated spirits may be withdrawn from the warehouse upon a permit issued in due form by any person who has complied with the provisions of the law, and filed the necessary application and bond with the collector of internal revenue in whose district the methylated spirits are to be used; the sale, removal, transportation, and use of such methylated spirits to be under prescribed regulations and bonds. Heavy penalties are prescribed for the purification, by any means, or the use, of such purified methylated spirits.

It will be seen from this review of the legislation on the subject, that the purification of methylated spirits is made unlawful, from which one might conclude that this process does not render the spirits altogether unfit for drinking-purposes when properly purified.

Having been requested by the commissioner of internal revenue to make experiments for the purpose of ascertaining whether such spirits could be demethylated, the experiments were made, and my report on the subject was published in the "Annual Report of the Commissioner of Internal Revenue," lately issued.

I now beg leave to submit to the members of the society some of the samples of distillates and artificial liquors produced, and let them judge for themselves how far I have succeeded in making a drinkable compound.

Ten per cent of the methyl alcohol was used for adulteration as being the largest amount known to me, when the experiments were carried out, as being legally permitted. The provisions of the Canadian law I did not learn of till after my report was written. As soon as I have some leisure, I intend trying to purify 25 and 50 per cent of adulteration.

The loss was, for the reasons stated in my report, much greater than would happen on a commercial scale; and, as long as there is a high tax on distilled spirits, a large loss might take place in purifying methylated alcohol, and yet render the illegal process profitable enough for unscrupulous persons to take the risk of detection.

Since the bill has been introduced a strong opposition to its provisions has been developed in the large wholesale and retail drug trade, and the *Oil, Paint, and Drug Reporter* has lately been devoting a great deal of space to the views of the most prominent dealers. They are of the general opinion that alcohol should be free to all, or not at all; that the small druggist who now prepares a great many, if not most, of his medicines, etc., would be driven out of the business, as he could not afford the bonded storeroom, etc., and be compelled to purchase from a few large firms who could readily afford to comply with all the necessary regulations; and, lastly, that the supervision at all times of revenue officers over their business is distasteful to them. A great many of them state, that, even if the alcohol was methylated, it would most certainly have to be purified before they could make use of it.

The great supporters of the measure are of course the alcohol-producers, who see in its provisions an increased market for their product.

ELECTRICAL NEWS.

Dissipation of Fog by Electricity.

SOME remarks in the editorial columns of the *London Electrician* have called forth a letter from Professor Lodge on the subject of the dissipation of the London fogs by means of electric discharges. At the Montreal meeting of the British Association, in 1884, Professor Lodge described some experiments in which he condensed smoke by means of a brush discharge from points connected with a static electric machine. The subject was an interesting one, and attracted considerable attention at the time; but it seems that no experiments on a large scale have since been attempted. A number of possible applications have been suggested, — for example, it has been proposed to use an electric discharge to dissipate the dust-particles in flour and other mills, which have been the cause of several disastrous explosions, — but the efficacy of the plan has not been tried. In the letter referred to, Professor Lodge states that he has been deterred from experimenting chiefly on account of the great initial expense necessary for a trial on a large scale, — an expense which he estimates to be in the neighborhood of five thousand dollars. As to the form of experiment, he is not sure that a battery of an enormous number of cells would not be the most likely plan. So far, the largest experiment that Professor Lodge has made has been the clearing of a smoke-filled room; but the results were so encouraging, that he does not despair of condensing the fog in a stagnant atmosphere. He has applied to the trustees of the Elizabeth Thompson fund in this country for a grant of five hundred dollars with which to continue his work, but has not yet heard the result of his application. The matter is a most interesting one. We have an entirely new field for electrical application, with a very substantial promise of reward for success. There are a number of possible applications of the process, — the clearing of smoke from tunnels, the dissipation of dust-particles in mills, and the general abatement of the smoke nuisance that is so unpleasant in manufacturing towns.

TRIALS OF THE SUBMARINE BOATS "GYMNOTE" AND "PERAL." — At a recent meeting of the French Academy of Sciences, Admiral Paris read a short paper on "The Submarine Boat 'Gymnote,'" which we lately described. He was most enthusiastic as to its success, and in the course of his remarks said, "In short, we are able to say that the 'Gymnote' moves and steers equally well above or below the surface, that it can be kept accurately at the desired depth, that its speed is all one could expect, that respiration is unimpeded, and that down to a certain depth it is easy to see. M. Tédé says that Captain Krebs's electric motors are marvels of lightness and precision, and that this important part of the boat has been carried out in a most masterly manner. The energy available amounts to 240 horse-power hours. So complete a success would have been impossible without the scientific ingenuity and minute care which M. Romázoff, naval engineer of Toulon, brought to bear upon every detail. Here, then, we have a solution of the submarine-boat problem. The first step has been taken. Better work will be done in the future. But, even as it is, the 'Gymnote' is capable of rendering good service." From *Engineering* we take the following: "The new Spanish submarine torpedo-boat 'Peral,' which has lately been tested with much success, is 72 feet long by 9.5 feet in diameter. It is fitted with a secondary battery of 600 cells, which supply the current to five electro-motors, two of which are of 30 horse-power each, and drive the propellers: the other three are only of 5 horse-power each. The boat has a speed of 11 knots on the surface, and 10.5 knots below. It can remain submerged for two days before the air requires to be renewed. It will be armed with Whitehead torpedoes." With the recent partially successful experiments with directable balloons, and these latest experiments with submarine boats, we may expect novel developments in warfare.

NEW RECKENZAUN TRAM-CAR. — The principal novelties in this car consist in the method of gearing the motors to the car-axles, and in the employment of a form of secondary battery on which Mr. Reckenzaun has been working for some years past. The ordinary practice of connecting the motor-shafts and car-axles is through two pairs of spur-gears, the ratios of the diameters giv-

ing the necessary reduction in speed, — about one turn of the car-wheels to ten or twelve of the motor. A single pair of gears would be sufficient for light work, but for climbing hills a single reduction would make the strain on the teeth too great. The efficiency of spur-gears is very great, and, when properly constructed, there is very little noise or jar. A much more compact arrangement, though a less efficient one, has been adopted by Mr. Reckenzaun. He uses a simple worm gearing, where the motor-shaft and car-axle are at right angles to each other. Such an arrangement has been generally avoided because of the supposed great loss through friction. From his own experiments, however, Mr. Reckenzaun concludes that the losses are greatly overestimated, and by taking especial care in the lubrication he has obtained efficiencies that compare favorably with the efficiency of spur-gears. But it is in the storage-battery that the greatest interest of the system lies. It does not seem to be any great improvement over the present battery in weight — the cells on a car weigh about two tons — or in efficiency, but it is claimed that the durability will be greater than that of the ordinary type. The plates are made by forming by pressure cylinders of active material, a sixth of an inch in diameter, and about an inch and a quarter long, putting them in a mould and casting lead around them. The cylinders are only about a tenth of an inch apart, while the thickness of the lead in which they are embedded is one-eighth of an inch. The advantages of this form of plate lie in the fact that the active material is held firmly in its place, and that the greater part of the expansion is in the direction of the length of the cylinders: so the chance of buckling is less, while a large active surface is offered to the action of the acid. The total weight of the car, with thirty passengers, is about seven tons and a half, and about five electrical horse-power is required to draw it on a level at a velocity of seven to eight miles an hour. On a hill with a grade of five per cent, the motors absorb twenty electrical horse-power. The car described has been built by Messrs. Stephens, Smith, & Co., and is for use in Melbourne, Australia.

SNOW-STORMS ON ELECTRIC ROADS. — The winter has thus far been so mild that electric railroads have hardly had a fair test as to their capability of working under adverse circumstances. One snow-storm in St. Joseph failed to stop the electric line there; and now we have news of a blizzard at Davenport, Io., through which the Sprague cars ran without interruption. In this last case the snow — of the heavy, damp variety — covered the streets to a depth of four or five inches, with drifts in places across the tracks. While this is satisfactory enough, it must be remembered that it is not the wet, slushy snow that is most to be feared, but the dry variety, that cakes on the track and prevents contact being made between the wheel and rail. The only safeguard against trouble from this last cause is to keep cleaning-cars going as long as the snow-storm continues. There is another difficulty, especially when a heavy overhead wire is used, and this is from the formation of a coating of ice or sleet, preventing the trolley from touching the wire. While in the two cases cited there has been nothing but encouragement, yet there have been rumors of troubles that occurred at Washington, at Lynn, and perhaps at Brockton, on account of snow and ice. These were no doubt caused by insufficient experience, and from neglecting common precautions, and were only small matters at the most, but they at least show that precautions must be taken.

APPLICATION OF ELECTRIC MOTORS TO MINING. — At the Drane Colliery, near Osceola, Clearfield County, Penn., Mr. F. M. Lechner has devised a most interesting application of motors to mining-work. A ten-horse-power Sprague motor is mounted on a truck running on rails, so it can be easily moved from one place to another. The weight of the machine is something less than a thousand pounds. The cutter to be operated is set in position in the space to be cleared, and is connected to the motor by a $\frac{5}{8}$ -inch rope belt, movable pulleys on jack-screws being so adjusted that the cutter can be operated at any angle from the motor. The latter is about thirty feet from the cutter, the tension of the belt being adjusted by moving the truck one way or the other. The machine runs easily and cuts well. By this plan three cutters can be worked from one motor, two being adjusted while the third is at work, the motor being moved from one to the other as it is needed. It was

found, on a preliminary trial of this apparatus, that by its use two men could excavate one hundred tons in ten hours, and that they can move the cutter as often as desired without any auxiliary aid. The efficiency of the dynamo and motor are each over ninety per cent, and, allowing ten per cent loss on the line, between seventy and seventy-five per cent of the power delivered to the dynamo can be called on at the motor for work. It has been estimated that the cost of equipping a mine with electric power is only half of that of compressed air, while the working expenses are about in the same proportion.

SCIENTIFIC NEWS IN WASHINGTON.

Some Habits of the Omahas. — Electrical Conductivity of Glass. — Fish Commission Experiments. — The Woman's Anthropological Society. — The Survey for Irrigation. — Indian Relics from Florida.

Some Habits of the Omahas.

The following statements have just been made by an Omaha Indian (Samuel Fremont) to Rev. J. Owen Dorsey: —

The Omahas used to blow the smoke of the pipe in six directions, up, down, and to the four winds, using a prayer in each case. The exact order in which the winds were addressed has been forgotten; but the smoker could pray to the being above first, if he wished, and then to the being below, or *vice versa*. The earth itself was spoken to as if it was a person. The formula was as follows: "One of you lies on his back [i.e., the earth], the other one sits above: both of you help me!" Then followed the petition, "Oh, ye who cause the four winds to reach a place, help ye me!"

White people think that the Omahas knew nothing about Wakanda (a higher power, the Mysterious Power) before the meeting of the two races; but that is not so. They had many old sayings, used before they met the white people, such as, "Wakanda has decided for him his own (child, descendant, etc.)." "Wakanda knew," and "Wakanda seems to have aided him." These were employed when an Indian met with unexpected good luck. But the Pawnees had many more sayings about Wakanda than the Omahas had.

Before the advent of the white people, the Omahas used to get the wild honey, which they called "bee-dung." Its present name is "bee-gum." They put the comb in a kettle, in which they let it melt and boil, skimming off the impurities. They used the sirup as the white people do molasses. Unless the bees were troublesome, they did not smoke them when they took the comb.

Electrical Conductivity of Glass.

Dr. C. Barus has just completed a protracted investigation on the effect of stress (traction torsion) on the electrical conductivity of glass at different temperatures between 100° and 360°. The question is of unique importance, because the conductivity of glass is wholly electrolytic. He finds that stress of the kind given materially increases conductivity; whence it follows that the time-rate at which molecular reconstruction takes place in glass is definitely greater when this substance is longitudinally extended or twisted than when it is free from such strain. The result has a direct bearing on the viscosity of the solid.

Fish Commission Experiments.

Marshall McDonald, United States fish commissioner, is making a comprehensive experiment in salt and fresh water aquariums. He has already constructed several aquariums on the lower floor of the building, and stocked them; and he is now building a large one, 120 feet long, under a separate roof. The commissioner said to the correspondent of *Science*, "I am going to bring the seashore to Washington, and assemble here a full representation of our marine life." He has sixty or seventy species already sporting in salt and fresh water tanks, one of the latter containing specimens of the earliest type of fresh-water fish, — the ganoids. •

The Woman's Anthropological Society.

One of the active scientific societies of Washington, and one whose work is of peculiar interest in that it is carried on solely by the sex sometimes supposed "incapable of generalizing," is the Woman's Anthropological Society. Despite the temporary retire-

ment of the president, Mrs. T. E. Stevenson, who is well known for her personal work among the Zuni, the society enters upon the fifth year of its existence with undiminished enthusiasm and vigor; Mrs. Sybil A. Carter (wife of the Hawaiian minister) and Miss Florence Spofford acting respectively as president and secretary. Two meetings were held during January. On the 5th the subject of discussion was "The Evolution of a Community (Amana)," as presented by Mrs. Anita Newcomb McGee. The author of the communication has been for several months engaged in investigating the communistic societies of the United States, nearly all of which she has visited. The more general results of her studies were laid before the American Association at Cleveland in August last. Some of the elements of success or failure in communistic organizations are obscure, and have seldom been perceived by writers on the subject; and these Mrs. McGee sought to develop and set forth by a study of the origin, growth, and relations to environment at every stage, of the most successful American community. The conclusions were in line with those stated at Cleveland, and summarized in the *American Naturalist* for September last. The meeting on the 19th was occupied in the presentation of a communication on "Russia and the Russians" by Mrs. Hunt, widow of the late minister to the Muscovite dominion. The habits, customs, and beliefs of the various classes of Russia were vividly portrayed; and the skill of artificers in certain Russian villages in the production of enamelled silver and other wares, etc.—arts handed down from generation to generation in Oriental fashion, and unknown elsewhere,—was illustrated by the exhibition of a collection of silver and fictile ware and unique textile fabrics.

The Survey for Irrigation.

Professor Thompson announces to the correspondent of *Science* that topographic parties of the United States Geological Survey engaged on the irrigation survey in New Mexico have completed their field-work for this season, and disbanded at Santa Fe.

An area of 3,500 square miles in the drainage basins of the Jemez and Rio Grande has been surveyed with sufficient detail to construct a map on the scale of two miles to an inch and contour interval of fifty feet.

This work has been under the immediate charge of Mr. Arthur P. Davis, who returns with most of his force to Washington to prepare final maps. One party, however, under charge of Mr. R. H. Phillips, will continue work in the lower Rio Grande valley, near El Paso, Tex., during the entire winter. A number of eligible sites for reservoirs and diverting dams have been located. It is estimated that sufficient water can be stored in the mountains about the head waters of the Jemez River to irrigate 150,000 acres of land where now the waters only serve about 4,000 acres.

Indian Relics from Florida.

Dr. Thomas Featherstonhaugh, a grandson of the famous pioneer geologist, has just returned from a visit to Florida, and has brought back an interesting collection of aboriginal remains. He thoroughly examined a mound of damp sand on the shore of Lake Apopka, about the geographical centre of the State, and farther south than any previous researches of the kind. The mound was fifty feet in diameter and fourteen feet high, and was covered with a dense growth of palmetto and other trees. It was found to be full of fragrant bones and pottery, so numerous that Dr. Featherstonhaugh estimates that there could have been no less than four hundred bodies deposited there. A few Venetian beads near the top indicated intrusive burials, but below four feet there were no evidences of any intercourse with whites. Four shapely hatchets were recovered, also a charm-stone, and numerous specimens of decorated pottery. The whole find was presented to Major Powell, and by him turned over to the Museum.

NOTES AND NEWS.

STANLEY'S letter to Tippto-Tip, which was recently published in the daily papers, contains no new information besides that which was conveyed in the recent telegrams. Stanley had succeeded in reaching Emin, and had returned to the Kongo in order to look after his rear guard. He was anxious to see Tippto-Tip, and invited

him to meet him at some distance from the Kongo, where he encamped. He intended to return to Emin. It was stated before, that Stanley's letters were detained for some unexplained reason at Stanley Falls Station, while the latest telegram said that there were no other letters besides the one mentioned, addressed to Tippto-Tip. The full information sent from Zanzibar has again proved incorrect, as was expected. The report of the arrival of a letter from Stanley had evidently been telegraphed to Zanzibar by way of London, where it was amplified and falsified, and came back through Reuter's agency. No reports on events in the Equatorial Province or on the upper Kongo coming from this source can claim any serious attention.

— The original portrait of Washington (right side of the face) by Gilbert Stuart, long thought to have been destroyed by the artist, seems to have been recognized in the hands of Dr. W. F. Channing of California, who inherited it from his distinguished father, Rev. William Ellery Channing, who obtained it from his uncle, Col. Gibbs. It is understood that both New York City and Chicago have made offers for it, to hang in their art galleries, and its ultimate destination is doubtful.

— Surgeon-Gen. Hamilton has had one of his expert assistants, Surgeon Kinyoun, carry on a series of experiments as to the effectiveness of new disinfectants. Phosphorus was the one taken for the chemical tests, with litmus-paper and micro organisms; and the conclusions arrived at were, "1st, that phosphoric pentoxide is a disinfectant to surfaces only; 2d, it has no penetrating power, and is altogether unfit for fumigation of any thing where penetration of the agent is desirable." So perishes the hope that the fumes of phosphoric pentoxide would be useful in extirpating the bacteria of disease.

— On the evening of Jan. 23 the Mathematical Section of the Philosophical Society held its forty-ninth meeting, elected officers, and heard and considered these papers: "A Brief Control for General Solutions of Normal Equations," by A. S. Flint; "On Napier's Logarithms," by Artemas Martin; "General Perturbations of the Minor Planets," by W. F. McK. Ritter.

— A bill has been introduced in the Legislature of Nebraska to provide for a geological survey of the State with special reference to economic purposes. It proposes co-operation with the United States Geological Survey. The professor of geology in the State University at Lincoln is made *ex-officio* State geologist, and the sum of five thousand dollars for each of two years is to be appropriated for the work.

— The War Department has granted to the Smithsonian Institution the privilege of erecting an astro-physical observatory on the heights of Arlington; its purpose being, as its name implies, the investigation of the physical constituents of the heavenly bodies.

— The bill for the establishment of a zoological park and museum stands much better in Congress than it did at the last session, and it looks at this moment as if the appropriation for the purchase of the land on Rock Creek would be granted. Professor Hornaday has made a strong impression on the committees which he has addressed, and has excited national emulation by contrasting this country with other lands in its neglect of opportunities to study its own natural history.

— The scientific bureaus of Washington are seeking more elbow-room. The ambition of the Geological Survey to have a new building (\$600,000) is matched by that of the Smithsonian, which seeks an appropriation of \$500,000 for the erection of a building in the other corner of the grounds. The plan contemplates a structure somewhat like the present, but without an interior court, and with two stories and a basement instead of one story.

— The National Museum has secured Col. James Stevenson's private collection of Indian relics, entirely Pueblo. It contains several hundred pieces, among them an example of pottery for which Tiffany recently offered \$250.

— Experiments are being made at Wheeling, W. Va., with a view to the utilization of natural gas as a fuel in the smelting of iron ore.

WE CALLED ATTENTION last week to the condition of affairs in the New York City Board of Education, and chronicled the triumph of political chicanery over public interest in the organization of the board for the coming year. Inasmuch as this situation in New York is of the greatest importance to educational interests all over the land, we shall revert to it from time to time, and endeavor to aid in forming an intelligent and conscientious public opinion which shall eventually displace the politicians and the politics that are now controlling the schools of the metropolitan city. The next contest will be over the report of the special committee on reform in the schools, the first instalment of which is now before the board, for action at its next meeting. The report is signed by Commissioners Webb, Cole, Sprague, O'Brien, Agnew, Dodge, Galloway, and Schmitt. It limits its consideration to a single point, and that perhaps the fundamental abuse of the New York City system; namely, the examinations of the children, as made by the city superintendent and his assistants, for the purpose of marking and grading the teachers and principals in the respective classes and schools. The committee believe—and we cordially indorse that belief—that many of the existing evils in the schools are the outgrowth and natural sequence of the methods now employed in a vain attempt to ascertain the true character of classroom work. The vicious system which is now in vogue has not (happily) the

sanction of any statute; but it has been built up by the present city superintendent and his predecessors, on the meagre provisions of a single by-law of the Board of Education itself.

This is the committee's account of the system: "The city superintendent or his assistants examine, orally and in writing, the children of every class in every school at least once a year. When the examination is to be made, a notice, varying in time from one to six days, is sent to the principal and teachers. The average time that the examiners spend with each class does not exceed half an hour. The main object of the examination of the pupils is to grade and mark the teachers, and to determine with what degree of success the classroom work is carried on. Marks are given by the examiners to the teachers on each subject; but the teachers are not informed what marks are awarded, nor is any provision made by which such information may be conveyed to them. The general results are reported to the trustees of the respective wards in which the teachers are employed; but as to how such results are reached, or in what particular subject a class may have failed, the record is silent. The teachers know that these marks (if they receive any attention) will form the basis upon which promotion, or worthiness for promotion, is to be determined. They know that in case of illness, when it may be necessary to come before the board, if the marks are below a certain standard, the salary expected may be seriously diminished; and that, in case two marks of 'fair' are awarded in succession, a summons will be received to appear before a committee of the board and answer to a charge of inefficiency as a teacher. At times, to the young, nervous, or inefficient teacher, the examination is a positive bugbear, and the examiner a natural enemy; and this estimate is speedily detected and shared in by the pupils. In such a class the examiner is not looked to for help, suggestion, or instruction; but he is regarded as one from whom all faults and weaknesses must be diligently concealed, and before whom the children are to make as brilliant a show as possible. His sole purpose is to assign a mark for each study, and that mark is to go down on the official record, to aid or mar the teacher's future advancement in the system."

This is the barbarous practice by which the executive officers control the schools and intimidate the teachers. Its mere statement is sufficient indictment. What are you going to do about it? say its beneficiaries. The committee is ready with an answer. After adequate examination, divide the teachers once and for all into two grades,—maximum and standard. All teachers who have been at least five years in the system, and who satisfy the principals with whom they have served, and the city superintendent (or, if they fail to agree, the committee of the Board of Education on teachers), are to be classed as maximum grade, and relieved of future examinations by the superintendent or his assistants, unless the principal reports that such a teacher is falling off and should be subjected to inspection. All other teachers shall be classed as standard grade, and shall receive not only visits of inspection, but help, from the assistant superintendents, in order to aid them in improving their work and in passing to the higher classification. The committee elaborates this principle, and reports the necessary amendments to the by-laws of the board, to place it in operation. The recommendations should be adopted, although it is reported that the "ring" will oppose them bitterly. We shall await the vote with interest.

THE VALUE OF MERCURIC CHLORIDE AS A DISINFECTANT.

IN *Science*, xii. p. 185, we quoted at considerable length from an article by Dr. W. B. Hills of Cambridge, Mass., which first appeared in the *Boston Medical and Surgical Journal*, in which the author of the article criticised in severe terms the recommendations of the committee on disinfectants, of the American Public Health Association, with reference to the use of mercuric chloride as a

disinfectant. In commenting on this article of Dr. Hills's, we said that Dr. Hills's criticisms dealt, not with generalities, but with particular errors which he claimed the committee had made, and that his criticisms put the committee on its defence.

In an exceedingly able article published in the *Boston Medical and Surgical Journal* of Jan. 3, 1889, Professor V. C. Vaughan, of the University of Michigan, and a member of the committee on disinfectants, meets the criticisms of Dr. Hills completely, and places the report of the committee on more substantial ground than ever. This reply of Professor Vaughan's we have deemed of sufficient value to give in full.

The report of the committee of the American Public Health Association on disinfectants, together with the experimental investigation of others, has given great prominence to the employment of mercuric chloride as a germicide. Recently (*Boston Medical and Surgical Journal*, Aug. 25, 1888) Dr. William B. Hills of Cambridge, Mass., has criticised the above-mentioned report so far as it recommends mercuric chloride. As this is a matter of great practical importance, I propose in this paper to notice the points raised in this criticism. Dr. Hills does not seem to have made any biological or chemical tests himself, but founds his opinion upon what he deems to be well-established facts. The critic uses severe language with reference to the committee, and asserts that "it is not creditable" that the committee should have made the recommendations referred to upon the experimental evidence presented.

In the first place, Dr. Hills states that corrosive sublimate is rendered insoluble when brought in contact with organic matter. He says: "It is, however, a well-known chemical fact that the corrosive sublimate is destroyed, or at least undergoes chemical changes, when brought into contact with organic matter. It is immediately converted by albumen to the insoluble albuminate of mercury. For this reason, albumen is recognized as the most efficient antidote in cases of poisoning by corrosive sublimate."

Now, let us inquire into the well-known chemical fact referred to by Dr. Hills. I endeavored to show in the report, which Dr. Hills criticises, that the albuminate of mercury is soluble in solutions containing organic matter, and that it does diffuse through such solutions; but, as Dr. Hills places his opinion against my experience, we will see what others say upon this point. Merck (*Merck's Bulletin*, August, 1888) of Darmstadt says that the albuminate of mercury, which he manufactures according to the formula of Schneider (*Pharm. Centralblatt*, 1888), is readily soluble in blood-serum, meat-broth, sodium chloride, etc. Every physician knows that the albuminate of mercury is used hypodermically on account of its ready solubility and non-irritating properties. For the preparation of this compound either egg-albumen, blood-serum, or peptone is used. Merck uses egg-albumen, while Filehne (*CLOETTA'S Lehrbuch der Arzneimittellehre*, 1887, S. 134) recommends the following formula: "15 grams of dry peptones, 10 grams of bichloride of mercury, 15 grams of ammonia chloride, and enough water and glycerine so that each cubic centimetre of the solution shall contain from two to four milligrams of mercuric chloride." Other formulæ are given by other authors. In one place Dr. Hills admits that the albuminate of mercury is "slightly soluble," but he says "the amount redissolved is very small." Filehne's solution contains more than two and a half drams of the bichloride. This amount would hardly be called "very small." When Dr. Hills says that albumen is recognized as the most efficient antidote in cases of poisoning by corrosive sublimate on account of the insolubility of the albuminate of mercury, he teaches a doctrine which, I must admit, is wholly new to me. Mercuric bichloride owes its corrosive properties to the avidity with which it combines with proteids. In cases of poisoning by this salt, we give the albumen in order to supply a proteid with which the poison can combine without injury to the walls of the stomach, and then we hasten to give an emetic. What would be the result if we should leave the albuminate of mercury in the stomach? If this compound is so insoluble, why do we give the emetic? The idea that the albuminate of mercury would not be readily absorbed by the stomach, is, to use some of Dr. Hills's vigorous English, "so absurd that it would not deserve serious notice were it not for the fact" that it has been suggested by one so eminent in the profession. If mercury forms an inert compound with albumen and other proteids, how is it that

we get constitutional effects by the administration of the compounds of this base in the treatment of disease? Are the contents of the stomach and intestines always free from proteids when the medicine is administered? The truth is, that the albuminate of mercury is insoluble in water, but is freely soluble in excess of albumen, in blood-serum, in meat-broth, in solution containing sodium chloride, etc. Indeed, all the mercury given medicinally is said by leading therapeutists and physiological chemists to be converted into the albuminate before it is absorbed. Filehne says concerning the absorption of mercury: "The salts of mercury soluble in water form first with albumen compounds, which, partly in excess of albumen, partly from the action of other substances, as sodium chloride, hydrochloric acid, etc., are soluble, so that the passage of these compounds into the blood as soluble albuminates is undoubted. The compounds insoluble in water are, by the action of sodium chloride and hydrochloric acid, converted into the sublimate, and this in turn into the albuminate." Nothnagel and Rossbach (*Handbuch der Arzneimittellehre*, sechste Auflage, S. 194) say that while the albuminate of mercury is insoluble in water, it is freely soluble in excess of albumen and in sodium chloride.

Dr. Hills again says: "Sternberg, in the *Medical Record* for Aug. 1, 1885, affirms positively that the albuminate (of mercury) is a potent germicide, but gives no facts in support of this statement. Klein's experiments, however, suggest that its germicide power is very slight at the most. Admitting, however, that it has such power, the amount redissolved is very small, and this is likely to be converted at once to the inert sulphide by the sulphuretted hydrogen present."

I have italicized the assertion to which I desire to give immediate attention. Here Dr. Hills is again wrong. Sulphuretted hydrogen does not decompose the albuminate of mercury. Every toxicologist knows this, and destroys the organic matter before he attempts to precipitate mercury from solutions containing proteids. In the report of the committee, where I show that the albuminate of mercury is soluble, I state that the organic matter was destroyed by potassium chlorate and hydrochloric acid, after which the mercury was precipitated with sulphuretted hydrogen. Nothnagel and Rossbach (*loco citato*) say that "from the albuminate of mercury one cannot precipitate the metal with sulphuretted hydrogen until the organic matter has been destroyed." If sulphuretted hydrogen precipitates mercury from proteid solutions, the mercury so precipitated is not combined with albumen, and the occurrence of such a precipitation shows that the mercury exists in excess above that taken up in the formation of the albuminate. The albuminate of mercury is not easily decomposed.

Again: Dr. Hills thinks that the alkalis formed in decomposing matter would precipitate the mercury. Nothnagel and Rossbach (*loco citato*) say that "if common salt be added to an alkaline solution of albumen, mercuric chloride will then fail to produce any precipitate." No one will question the existence of common salt in privy-vaults.

It is true that Klein's experiments suggest that the germicide power of mercuric albuminate is very slight at most. Indeed, Klein asserts (or rather did assert) that a one-per-cent solution of mercuric chloride is no more a germicide than is vinegar. Certainly no one will now champion this statement, although vinegar is not worthless as a germicide. Koch found that the spores of the anthrax bacillus will not germinate in a proteid solution if there be present one part of corrosive sublimate in three hundred thousand. And yet Dr. Hills, without having made an experiment, condemns the committee for recommending a solution of corrosive sublimate, one to five hundred, for the disinfection of the liquid discharges of cholera, typhoid-fever, etc.

Dr. Hills finds very strong language of condemnation for the report of the committee in recommending that the amount of bichloride found necessary to sterilize broken-down beef-tea be multiplied by two, and used for the disinfection of the liquid discharges from the bowels of patients with cholera, typhoid-fever, advanced tuberculosis, septic diarrhoea, etc. As he bases his condemnation upon the incompatibility (?) of mercuric chloride with albumen, he must suppose that these stools contain a large amount of soluble proteids. In this he is again wrong: such discharges do not contain large amounts of albumen or other soluble proteids.

Simon (BECQUEREL and RODIER'S *Pathological Chemistry*, p. 459) obtained the following results from the analysis of the fecal matters in cholera:—

Water	980.00
Solid matters.....	20.00
Fat.....	0.08
Extractive matter.....	4-80
Albumen and mucus.....	0.52
Chloride of sodium, lactate and acetate of sodium, and alkaline phosphates.....	13.40
Phosphate of lime and magnesia	0.60

The blood contains, according to Hammerston, from 2,677 per cent (horse) to 4,436 per cent (rabbit) of serum albumen; and yet, according to Von Ermengen, mercuric chloride in solution of 1 : 800 and 1 : 1,000 sterilizes blood. With these figures before us, can we say that "it is not creditable to a committee of the leading sanitary association of this country" to recommend a solution of mercuric chloride 1 : 500 for the disinfection of cholera stools?

Practically we know that mercuric chloride does efficiently disinfect substances containing a hundred times as much proteid as cholera stools contain. This is done many times every day in bacteriological laboratories. Gelatine plates and tubes, agar tubes, and blood-serum tubes, laden with all the known germs, are disinfected with a solution of mercuric chloride 1 : 1,000. In Koch's laboratory this is the only disinfectant used, and there has been no evidence of its failure. Plates-covered with colonies of the anthrax bacillus, the comma bacillus, etc., are immersed in the solution with the certainty that the sterilization will be complete. Old tube cultures are treated in the same way, and with the same result, whether they contain gelatine, agar, or blood-serum. Now, in the gelatine, one litre of beef-tongue contains 100 grams of gelatine, 10 grams of peptone, and 5 grams of sodium chloride. We have seen that the albuminate of mercury is made with peptone as well as with albumen, and there is nearly twenty times as much peptone in this mixture as there is albumen in cholera stools, and nearly two hundred times as much gelatine besides. Certainly no one will question the large amount of albumen in blood-serum. Is it not strange, if the albuminate of mercury is so "inert," that the disinfection of these cultures should be so successful? Even the evacuations of infants with green diarrhoea, containing a large amount of undigested food, do not contain as much proteids as do gelatine cultures, as is shown by the following analysis of Golding Bird:—

Water.....	900.00
Biliverdin, alcoholic extracts, fat, cholesterine.....	24.50
Ptyalin, watery extract, colored with biliverdin.....	11.25
Mucus, coagulated albumen, and hematin.....	56.00
Chloride of sodium, with traces of tribasic phosphate of soda.....	5.50
Tribasic phosphate of soda.....	1.75
Peroxide of iron.....	1.00

In the first report of the committee (1885) a solution of chloride of lime was given the first place for the disinfection of excreta in the sick-room, and a solution of mercuric chloride of the strength of 1 : 500 the second place. In the latest report (1888) carbolic acid has been given the second place, and mercuric chloride has not been recommended for this purpose. This change was made because the carbolic acid was believed to be sufficient, and not because the mercuric chloride was believed to be inefficient. In the light of the most recent experiments in this country and abroad, we believe that mercuric chloride, in the proportion named, would be effective in the disinfection of the liquid discharges of patients suffering from typhoid-fever or cholera, and that the recommendation made in our first report was justified by the experimental data then given, and not yet contradicted by any new evidence.

The committee called attention to the action of mercuric chloride on lead pipes in its first report, and this influenced it in substituting carbolic acid for mercuric chloride for disinfecting the excreta in the sick-room.

To return to our critic, the broad statement is made, that "an examination of the report of this committee fails, however, to bring to light the slightest particle of evidence upon which such a recommendation could have been based;" viz., the disinfection of excreta with mercuric chloride. Dr. Sternberg, chairman of the committee, made extended researches upon the germicide power of this agent several years before (1883) the committee was appointed, and to those experiments reference is made in the first report. It is for

this reason that extended experimental researches were not made with this agent in 1885. However, a number of experiments were made, and recorded in our report. These show that even the solid or semi-fluid feces of a healthy person may be sterilized by the use of the solution recommended by the committee, provided that they are broken up so as to be fairly exposed to the action of the disinfecting agent. Moreover, the fact is recorded that a certain amount of the mercurial salt remained in solution at the end of twenty-four hours, as shown by a deposit of mercury on a copper wire (experiment of Sept. 8). Yet our critic, without recording a single experimental observation of his own, states that there is not the slightest particle of evidence upon which our recommendation could have been based.

One who has given no special attention to chemistry may be pardoned for not being acquainted with the chemical nature of the albuminate of mercury, but certainly any one who had read our report could not have made the sweeping assertion which we find in Dr. Hill's criticism.

FIFTH ANNUAL REPORT OF THE BUREAU OF ETHNOLOGY.

THE "Report of the Director of the Bureau of Ethnology for the Year 1883-84" has just been issued, bearing the date 1887. The long delay of this report, which is caused by the pressure of work in the Government Printing-Office, must be greatly regretted, as the interest of science demands that scientific publications of the character of those accompanying the report be known as early as possible. The knowledge that certain statements and opinions are about to be published always acts as a drawback upon the progress of the special field of science, as most workers will delay further investigations until these publications are issued. While a few branches of science may not be very adversely affected by these delays, such is not the case in the science of anthropology, in which the most energetic and unceasing field-work is absolutely necessary, as the relics of ancient times, as the natives and their customs, are vanishing with steadily increasing rapidity. Publications of such importance as the one under discussion always prove an incentive to increased activity. The opinions and suggestions expressed in the papers accompanying the report do not fail to influence the progress of investigations. For all these reasons a more rapid publication of the annual reports is very desirable.

Major Powell, in the first part of the report, gives a brief review of the work carried on by the bureau. The scope of the researches is constantly increasing. In the year 1883-84 the mound-explorations were continued. Messrs. Stevenson and Mindeleff carried on archaeological researches in the South-west, while Mr. Frank Cushing devoted himself to further studies on the Zuñi. Linguistic work was done among the Iroquois, in California, and among the Navajo. While the final results of the works of the bureau will be published as "Contributions to the Ethnology of the North American Indians," the papers accompanying the reports generally treat certain phenomena of Indian life or art in the form of monographs or reports on peoples on which no material for exhaustive reports is obtainable.

Of the latter class, we notice in the present volume Rev. Clay MacCauley's description of the Seminole Indians of Florida,—an interesting sketch of the life and state of this small tribe living in the most inaccessible portion of the southern half of the peninsula.

The elaborate paper on "The Cherokee Nation of Indians: A Narrative of their Official Relations with the Colonial and Federal Governments," by Charles C. Royce, is an historical document of the greatest importance, the history of this great confederacy in its conflicts with the white settlers encroaching upon their territory being traced fully and exhaustively. The paper is an illustration of a work of wide scope undertaken by the bureau,—an historical atlas of Indian affairs, showing, upon a series of State and territorial maps, the boundaries of the various tracts of country which have from time to time been acquired through the medium of treaty stipulations or act of Congress from the several Indian tribes resident within the present territory of the United States. Accompanying the atlas will be one or more volumes of historical text, wherein will be given with some detail a history of the official

relations between the United States and these tribes. This will treat of the various negotiations for peace and for the acquisition of territory, the causes rendering such negotiations necessary, and the methods observed by the government through its authorized agents in this diplomacy, as well as other matters of public concern growing out of the same. The eminent value of this work to the historian is self-evident, and the laborious care bestowed by Mr. Royce upon the carrying-out of this plan promises that it will be at once an exhaustive and clear treatment of this important part of the history of our Republic.

The first paper of the volume is Professor Cyrus Thomas's treatise on "Burial-Mounds of the Northern Section of the United States." Since this paper was written, much evidence has accumulated which has been outlined in a bulletin of the Bureau of Ethnology. It corroborates the views expressed by Professor Thomas in the present report.

His conclusions, as set forth in this paper, are that different sections of the country were occupied by different mound-building tribes, which, though belonging to much the same stage in the scale of culture, differed in most instances in habits and customs to a sufficient extent to mark, by their modes of burial, construction of their mounds, and their works of art, the boundaries of the respective areas occupied. He furthermore concludes that each tribe adopted several different modes of burial, depending, in all probability, to some extent upon the social condition, position, and occupation of the deceased. The custom of removing the flesh before the final burial apparently prevailed very extensively among the mound-builders of the northern sections; the bones of the common people being often gathered together, and cast in promiscuous heaps, over which mounds were built. Usually some kind of religious ceremony was performed at the burial, in which fire played a prominent part; but, notwithstanding the very common belief, there is no evidence whatever that human sacrifice was practised. The builders of the mounds had not reached a higher culture than that attained by some of the Indian tribes found occupying the country at the time of the first arrival of Europeans. Professor Thomas concludes his treatise by expressing his opinion that the mound-building age cannot have lasted longer than about a thousand years, and that it continued to be practised in several localities in post-Columbian times.

There remain two papers to be noted, both of peculiar interest, — the one by Dr. Washington Matthews, who gives a very detailed description of one of the remarkable religious ceremonies of the Navajo; the other by Mrs. T. E. Stevenson on the religious child-life of the Zuñi.

Dr. Matthews describes the long ceremonies of the Mountain-Chant, and gives the long myth which is the foundation of these ceremonies. His paper concludes with the original texts of the songs, and translations of the same. It is impossible to give an account of the interesting contents of this essay, which is full of new facts of the greatest importance to the student of anthropology.

Mrs. Stevenson's paper is of a somewhat similar character, treating of the connection between certain customs and myths. This field of study, so ably taken up by Dr. Matthews and Mrs. Stevenson, has so far received comparatively little attention; and yet it is one of the most important for the study of the human mind and of the growth of institutions.

The publications of the Bureau of Ethnology mark every one a long step forward in our knowledge of man in America, and are therefore anxiously awaited by all students. We hope that the following volumes may be issued at shorter intervals, that the important material contained in them may soon become public property.

BOOK-REVIEWS.

The Birds of the West Indies. By CHARLES B. CORY. Boston, Estes & Lauriat. 8°.

IN preparing the present work, Mr. Cory examined a large series of birds from nearly all the islands of the West Indies, the combined collections representing many thousands of specimens. He made five trips to different parts of these islands, besides which a

number of collectors were sent out, for the purpose of obtaining as complete a series as possible. Several of these collectors were engaged upon their task from six to eighteen months, and it is fair to assume that their collections contained nearly all of the resident species of the islands which they visited. Some of these collections proved especially interesting, being very rich in novelties, the collections of one person containing no less than seventeen species new to science.

Most of the matter contained in the present work appeared originally in the *Auk* during the years 1886, 1887, and 1888; but since that time a large number of species have been added to the West Indian avifauna which were either new to science or had not been previously recorded from that locality. Descriptions of these are given in an appendix, unless included in their proper order in the body of the work. A number of alterations and corrections have been made in the original plates, and several new illustrations have been added. No descriptions are given of well-known North American birds, and the references to such are mainly restricted to the citation of works and papers on West Indian ornithology.

The excellent mechanical make-up of the book admirably supplements the painstaking and thorough work done by Mr. Cory in its preparation.

Louis Lambert. By HONORÉ DE BALZAC. Tr. by Katherine P. Wormeley, with introduction by George F. Parsons. Boston, Roberts Bros. 12°. \$1.50.

BALZAC seems to have written this story for the express purpose of making known what he would call his philosophy, which is a curious compound of mysticism and nonsense. The hero of the tale, Lambert, is introduced when a boy, and considerable space is given to his experience and reflections while at school. At a later time, after a season in Paris, he falls in love with a titled lady, and marries her. Unfortunately, however, he becomes insane just before his marriage, and remains so ever after, and dies while still a young man. The "philosophy" of the book is contained partly in his conversations and letters, but chiefly in some papers composed after he became insane; and these latter seem to be the dearest to the soul of Balzac. The doctrine expressed in them is of the occult kind, as will be seen from the following specimens: "Here below all is the product of an ethereal substance, the common base of several phenomena. . . . Will is a fluid, the attribute of every being endowed with motion. . . . Facts are nought; they do not exist; ideas alone exist. . . . All things here below exist only by motion and by number. . . . There is a number which impurity cannot transcend — the number wherein creation is finished. . . . Three and seven are the two great spiritual numbers" (pp. 138-148). Besides the story that gives name to the book, there are two others in the volume; but there is little connection between them and Louis Lambert; and the second of them, Gambara, we have found intensely disagreeable. The introduction to the book, which is as long as the leading story, is partly a summary of Balzac's ideas, and partly an attempt to reconcile them with the teachings of physical science, — an attempt which, as may be supposed, is not very successful.

AMONG THE PUBLISHERS.

GINN & Co. announce "An Introduction to the Poetry of Robert Browning," by William John Alexander, Munro professor of English language and literature, Dalhousie College and University, Halifax, N. S., and formerly fellow of Johns Hopkins University, to be published in February. The book opens with an account of Browning's most striking peculiarities in method and style, and attempts to find an explanation of these in the conditions amidst which the poet has worked, and in the nature of the themes which he treats. In the next place, an exposition is given of those general ideas pervading his work, which can only be gathered from the study of many of his poems, and yet are needful for the full understanding of almost any one of them. This exposition is contained in a series of chapters on "Browning's Philosophy," "Christianity as presented in Browning's Works," and "Browning's Theory of Art." These chapters are followed by a brief chronological review of his writings, and characterization of his development. The various points treated throughout the introduction are illustrated

by a series of selected poems furnished with careful analyses and copious critical comments. It is hoped that by thus unfolding, in a few typical examples, the characteristics and merits of Browning, the reader may at once be enabled to acquire a real knowledge of his poetry, and be prepared for further unassisted study of his work. The attention of those already familiar with Browning is especially directed to the analysis of "Sordello," much fuller and more exact, it is believed, than any heretofore published.

—The *Revue Philosophique de la France et de l'étranger*, edited by Th. Ribot, professor at the Collège de France, has just commenced its fourteenth year. This periodical is published monthly, each number containing about one hundred pages. Special attention is paid to psychology and its indispensable auxiliaries, anatomy and physiology of the nervous system, pathology of the mind, anthropology, and inductive and deductive logic. Reports on the current philosophic literature enhance the value of the journal.

—The *Revue Historique* for 1889 continues to be of great interest. It is published bi-monthly, and, besides original contributions, each number contains notes of general interest, unpublished documents, and a useful bibliography. It is published by F. Alcan, Paris.

—Neumayr, the distinguished paleontologist of Vienna, has just published through Tempky a first stout imperial octavo volume of a work upon which he has been engaged for many years, in which he is to review the entire series of extinct animals in the light of the derivative theory of organic life. Under the title "Die Stämme des Thierreiches" he discusses the lower forms of life, leaving the mollusks, arthropods, and vertebrates for future volumes. The purely theoretical side of the subject and the purpose, with which he began his studies, to search in every quarter for proofs of the alteration of forms, have gradually, in working out his scheme, given place to a critical and scholarly investigation into the general morphology of fossil animals; and his work will thus prove of the utmost value not to the paleontologist only, but equally to the zoologist. No living naturalist is more competent than he to perform the task. In an introduction of over 150 pages he discusses the general questions of the relations of the derivative theory to paleontology in a masterly manner; subsequent chapters take up successively the protozoa, coelenterates, echinoderms, worms, and molluscs. The second volume, treating presumably of the remaining invertebrates, is, he tells us, nearly completed. The work forms an excellent complement to Zittel's nearly completed "Handbook of Paleontology."

—The *American Naturalist* for January (New York, Leonard Scott Publishing Company) will contain an article on "Primitive Architecture," by Mr. Barr Ferree, in which is traced the various sociological causes that have influenced the form and construction of the dwellings of primitive peoples. The same number will contain an article on "The Food of the Owls," by Dr. W. S. Stodge; on "The Ancient Glaciers of North Wales," by Professor Evans; and on "Lichens," by Professor Williams. The departments of the magazine will present their usual summary of the progress of all branches of natural science within the past month.

—A remarkably successful attempt at photographing the very shy Big-horn, or Rocky Mountain sheep, will be described in the February *Scribner* by Frederick H. Chapin, who succeeded in taking a group on Table Mountain, Colorado, in 1887. The photograph has been engraved to accompany the article. In the same number Austin Dobson will recall some memories of "Old Vauxhall Gardens" in its prime,—the days of Walpole, Fanny Burney's "Evelina," and Fielding's "Amelia." The article will be fully illustrated from old prints. In his article on Sir Walter Scott, Ex-President Andrew D. White of Cornell will say of him, "Never was there a more healthful and health-ministering literature than that which he gave to the world. To go back to it from Flaubert and Daudet and Tolstoi is like listening to the song of the lark after the shrieking passion of the midnight pianoforte; nay, it is like coming out of the glare and heat and reeking vapor of a palace ball into a grove in the first light and music and breezes of the morning." George Hitchcock, the artist whose contribution to

Scribner's Christmas number on "Botticelli" will be recalled, will appear in the February number, with a second article on "The Picturesque Quality of Holland," this time describing "Interiors and Bric-a-brac." Mr. Hitchcock has for many years lived in Holland. The February instalment of Robert Louis Stevenson's romantic novel, "The Master of Ballantrae," will describe the pathetic persecutions of, "Mr. Henry," and the unexpected return of the "Master." Brander Matthews will have in the number an ingenious and fanciful story, entitled "A Family Tree."

—Charles A. Wenborne, Buffalo, N.Y., announces for immediate publication an "authorized" American edition of Laurence Oliphant's "Scientific Religion; or, Higher Possibilities of Life and Practice." This book, when first published in London eight months ago, immediately became a subject of such wide-spread interest that the author felt impelled to arrange, also, so says Mr. Wenborne, "for its publication in the United States. He visited this country last summer, and upon his return to England was taken down with the fatal illness that terminated his eventful life on Dec. 23. The author's intention to give a distinct introduction to the American edition was carried out by his newly wedded wife, an American lady, born Dale Owen, who had for some time been a distinguished co-worker in that field of religio-philosophical science of which Laurence Oliphant may be regarded as the most brilliant, most profound, and most advanced explorer of modern times."

—*The Green Bag*, "a useless but mildly entertaining magazine for lawyers," to be edited by Horace W. Fuller, is announced by Charles C. Soule, Boston. It is to be a monthly, intended to interest and entertain lawyers. It will cover legal history, antiquities, biography, news, gossip, and facetia, together with correspondence and book notices. The first number, to be published this month, will contain an excellent portrait of Chief Justice Fuller in his robes of office. Each subsequent number will contain the portrait of some distinguished judge or lawyer. There will also be illustrated articles, among them a series of papers upon the leading American law schools.

—We have received two pamphlets by Charles H. Fitch of Denver, Col., on "Womanhood Suffrage" and on "The Fallacy of Free Land" (published by the author), but we find nothing new or valuable in either of them. The first presents the usual arguments in favor of woman suffrage, but in an obscure and rather grandiloquent style. The second is an argument for the Henry George theory of rent, and the injustice of private property in land, but contains nothing that has not been repeatedly said by others. The subjects treated, like some other political and economic questions of the present time, have been discussed so much, that unless one can say something new on them, or can present the old arguments in a superior form, there seems to be no good reason for his treating them at all.

—One of the best known of the English journalists in America to-day is Mr. W. T. Stead, the managing editor of the *Pall Mall Gazette*. As a journalistic worker, Mr. Stead has seldom had an equal; and recently, when offered a vacation, he took it on the condition that he might work. The vacation became a trip to Russia, the result of which is to be published in a stout volume by Cassell & Co. While the political situation is the burning question of the book, he has time to visit Count Tolstoi, and to give the reader pictures of Russian life painted with a realism that M. Verestchagin might envy.

—The *American Anthropologist* for the first quarter of 1889 comes to us in a handsome brown cover and a generally improved typography and appearance. It contains Washington Matthews's article on the curious "Navajo Gambling Songs," and especially the melodies which accompany the winter game of Kesticé; Otis T. Mason's examination of the beginnings of the carrying industry, an illustrated article; "On Alternating Sounds," by Franz Boas; "Folk-Lore of the Siletz Indians," by J. Owen Dorsey; a summary of current methods of voting, by James H. Blodgett; and a variety of original notes and news. The feature of this quarterly which will excite most attention is the first instalment of a bibliography of anthropological literature, by Robert Fletcher, who has undertaken the

valuable service of preparing a similar compilation for each number.

— So strong a feeling has been manifested in this country against the publication of a cheap pirated edition of Professor Bryce's noble work on "The American Commonwealth," says the *New York Tribune*, that it is hardly possible that any publisher will undertake it. The *Boston Advertiser* says, "Professor Bryce's materials were gathered by the most patient, candid, and acute inquiry in this country, and represent many years of labor on his part and that of his American assistants. He has made admirable use of them in the preparation of a work universally recognized as a monument to our Commonwealth, and of the foremost importance to all students of our institutions and people. For such a monograph the nation cannot afford to show itself ungrateful. If a publisher attempts to put an edition of this work on the market to defraud the author and discredit the nation, his attempt should be pilloried as peculiarly disgraceful, and the edition should be boycotted by honest book-buyers."

— E. Hollenshade, 136 Lake Street, Chicago, has published what he calls a "gored map" of the northern and southern hemispheres, which is a novelty well worthy the attention of educators and students. It is designed to obviate the necessity of a globe in the study of geography, and conveys an adequate conception of the exact relations borne by one portion of the earth's surface to every other.

— Messrs. Longmans & Co. are about to publish in New York two new books of fiction. One is "A Nine Men's Morrice, Stories Collected and Recollected," by Mr. Walter Herries Pollock, the editor of the *Saturday Review*. Most of these striking stories have a tinge of the supernatural. The other book is "A Dangerous Cat's-paw," by D. Christie Murray, and his brother Mr. Henry Murray. This is at once a story of ingenuity and mystery, with the robust humanity common to Mr. Murray's other novels.

— "Chancellor Chess, or The New Game of Chess," by Ben. R. Foster, A.M., chess editor of the *St. Louis Globe Democrat* for more than ten years, is announced as in press. Seventy pages are devoted to the new piece called "The Chancellor," containing a history of its origin, "with forty problems, and a number of games illustrative of its beauties, powers, and possibilities." It is published by the author, in St. Louis, Mo.

— Charles Scribner's Sons published last week "The History of the Roman Republic," abridged from the history of Professor Mommsen, by C. Bryans and F. J. R. Henty, which presents the salient points of the original in a form suitable for use in schools and colleges and for the convenience of the general reader; "The English Restoration and Louis XIV., from the Peace of Westphalia to the Peace of Nimwegen," by Osmund Airy, in the Epochs of Modern History Series; and "The Validity of Non-Episcopal Ordination," the Dudleian lecture, by Professor G. P. Fisher.

— Scribner & Welford have just issued a new edition of Barry E. O'Meara's "Napoleon at St. Helena," in two volumes, with numerous illustrations in colors and black and white. A refutation of Croker's diatribe which appeared in 1822, and a Napoleon calendar, have been added by the editors. They have also just ready a new edition of D'Anvers' "History of Art;" a new edition, in the Ideal Series, of "Sartor Resartus," with an etched portrait of Carlyle; an *édition de luxe* of "Kensington, Picturesque and Historical," by W. J. Loftie, with upwards of 300 picturesque and delicate illustrations by W. Luker, jun.; and the first volume of Professor Franz Delitzsch's "Commentary on the Book of Genesis," of which this house (by special arrangement of the author) is publishing a translation of the fifth edition, thoroughly revised, and in large part rewritten.

— According to *The Publishers' Weekly*, the new departure of the *New York Ledger* attracts much notice. Mrs. Burnett and Mr. Stevenson are engaged to write for the *Ledger*, and in the current number a learned paper by Dr. McCosh is found beside some very lurid fiction.

— *The American* states that Collier's *Once a Week* is a sort of eagle among the doves. It is said to offer "rates" to the most

popular writers, such as the magazines, with all the pressure of competition, decline to pay, and to threaten a consequent monopoly of much of the high-priced talent. Its liberality confounds the older journals.

— Mr. Thomas Stevens, whose ride around the world on a bicycle is known to all, is now on his way to find Stanley, sent through the enterprise of the *New York World*. We reproduce this week his portrait. Mr. Stevens's famous ride stands unequalled in the history of travel, and his own story of it, in "Around the

Yours sincerely
 Thos Stevens

World on a Bicycle" (published by Charles Scribner's Sons) is told in a manner which charms the reader from the beginning. His escapes from death were marvellous, and thrilling incidents were daily occurrences; and his narrative of them shows him to be as good a writer as wheelman. The work contains over 200 illustrations. The work is divided into two volumes,—"From San Francisco to Teheran," and "From Teheran to Yokohama." The volumes are, however, sold singly.

— From among the several hundred books published during 1888 by J. B. Lippincott Company, we note the following as likely to be of special interest to our readers, aside from works of fiction: "The Animal Life of Our Sea-Shore," by Angelo Heilprin (fully illustrated); "Beethoven," a memoir, by Elliott Graeme, with an introductory essay by Dr. Ferdinand Hiller; "Béranger's Songs and Poems," selected by W. S. Walsh (with steel plate illustrations); "Botany," for academies and colleges, by Annie Chambers-Ketchum (250 illustrations); "Boys' Own Book of In-door Games and Recreations," edited by G. A. Hutchison (over 700 illustrations); "Chambers's Encyclopædia," Vols. I. and II., edited and published under

the auspices of W. and R. Chambers, Edinburgh, and J. B. Lippincott Company, Philadelphia, entirely revised and rewritten, complete in ten volumes, to be issued at intervals; "The Chemical Analysis of Iron," by Andrew Alexander Blair (illustrated); "The Complete Works in Verse and Prose of Percy Bysshe Shelley," edited, prefaced, and annotated by Richard Herne Shepperd, each volume complete in itself, in sets of five volumes; "Diseases of the Skin," a manual for practitioners and students, by W. Allan Jamieson, M.D. (illustrated with woodcuts and colored plates); "Embroidery and Lace," by Ernest Lefévre, translated from the French (with about 150 illustrations); "Francis Bacon, his Life and Philosophy," by John Nichol; "Girls' Own In-door Book," edited by Charles Peters (over 150 illustrations); "Half-Hours with the Best Foreign Authors," translations selected and arranged by Charles Morris, four volumes; "Hand-Book of Games," new edition, comprising whist, draughts, billiards, etc., edited by Henry G. Bohn; "Highways and Horses," by Athol Maudslay (with numerous illustrations); "Inebriety: its Causes, its Results, its Remedy," by Franklin D. Clum, M.D.; "Insects Injurious to Fruits," by William Saunders; in the International Statesmen Series, edited by Lloyd C. Sanders, "Lord Beaconsfield" (by T. E. Kebbel), "Viscount Palmerston" (by Lloyd C. Sanders), "Prince Metternich" (by Col. G. B. Malleson, C.S.I.), "O'Connell" (by J. A. Hamilton, fellow of Magdalen College, Oxford), "Lord Bolingbroke" (by Arthur Hassall), and "Peel" (by F. C. Montague); "Intracranial Tumors," by Byron Bramwell, M.D. (116 illustrations); "Jesus in Modern Life," by Algernon Sydney Logan; "Laconisms, the Wisdom of Many in the Words of One," by J. M. P. Otts, D.D.; "Large Fortunes; or, Christianity and the Labor Problem," by Charles Richardson; "Life of Lamartine," by Lady Margaret Domville (with portrait); "The Life of the Right Hon. W. E. Forster," by T. Wemyss Reid, two volumes (with portraits and other illustrations); "Memoirs of Count Grammont," by Anthony Hamilton, edited with notes by Sir Walter Scott (with portrait of author, and 33 etchings by L. Boisson, on India paper); "Modern Science and Modern Thought," by S. Laing (fifth edition); "Paradoxes of a Philistine," by William S. Walsh; "Patriotic Reader," by Henry B. Carrington; "A Popular History of Music, Musical Instruments, Ballet, and Opera, from St. Ambrose to Mozart," by James E. Matthew (150 illustrations); "Spinoza," by John Caird, principal of Glasgow University (with portrait); "Tenure and Toil; or, Rights and Wrongs of Property and Labor," by John Gibbons; "Therapeutics: its Principles and Practice," by H. C. Wood, M.D. (new seventh edition); "A Treatise on Mine-Surveying, for the Use of Managers of Mines and Collieries," by Bennett H. Brough (with numerous illustrations); "Two Centuries of Irish History, 1691-1870," with introduction by James Bryce, M.P.; "United States Dispensary," new sixteenth edition, by H. C. Wood, M.D., Joseph P. Remington, and Samuel P. Sadtler; "Untrodden Paths in Roumania," by Mrs. Walker (with 78 illustrations); "Walks in Palestine," the letterpress by H. A. Harper (illustrated by 24 photogravures from photographs taken by C. V. Shadbolt, Esq.); "With the Camel Corps up the Nile," by Count Gleichen, nephew of Queen Victoria (with numerous illustrations); " Worcester's New Academic Dictionary," entirely new edition, the etymology of words a distinctive new feature, reset from new type, and printed from new plates; " Worcester's New Comprehensive Dictionary," entirely new edition, containing over 48,000 words in common use, with an appendix of 15,000 proper names, new illustrations, reset from new type, and printed from entirely new plates; and "The Writer's Hand-book, a Guide to the Art of Composition," forming a new volume of the Reader's Reference Library.

— Houghton, Mifflin, & Co. will shortly publish a volume of the late Asa Gray's reviews of botanical literature during the past fifty years, selected and edited by Professor C. S. Sargent.

— F. W. Christern, New York, will be the American agent of Santa-Anna Néry's elaborate work on Brazilian folk-lore, recently published in Paris. The book has a preface written by Prince Roland Bonaparte.

— *The Chautauquan* for February contains, among other things, "Gossip about Greece," by J. P. Mahaffy of Dublin University; "Socrates," by Thomas D. Seymour of Yale University; "Greek

Art," by Clarence Cook; "Music among Animals," by the Rev. J. G. Wood; "Taxation," by Professor Richard T. Ely of Johns Hopkins University; "Hospitals," by Susan Hayes Ward; "The Power-Loom," by Charles Carleton Coffin; "A Summer Meeting in Oxford," by Herbert B. Adams; "The City of the Sultan," by Eugene L. Didier; "The Modern Migration of Nations," by Hjalmar Hjorth Boyesen; "Petroleum in Russia," by P. de Tschihatchef; "The Carlisle Indian School," by Frances E. Willard; "Robert Elsmere: An Open Letter from the Rev. Lyman Abbott;" "The Sons of Eminent Men in Office," by Mrs. Carl Barus.

— A prospectus of a monthly magazine to be called *Poet-Lore*, and to be devoted solely to the illustration of Shakspeare and Browning, and to the comparative study of poetic literature, has just been issued. It is signed by Charlotte Porter, late editor of *Shakspeariana* (from August, 1886, to December, 1888), and Helen A. Clarke, whose address is 223 S. 38th Street, Philadelphia. Dr. W. J. Rolfe will contribute to its study department a series of questions and helps for the study of Shakspeare's plays, beginning in the February number with "Love's Labor's Lost," and continuing with later plays. The "Explanatory Index to Allusions in Browning's Pauline," given in the January number, will be continued through the later poems. Dr. Horace Howard Furness' lectures on Shakspeare, delivered at the University of Pennsylvania, will appear in extracts made by Dr. Furness for this publication. W. H. Wyman's "Bacon-Shakspeare Bibliography" will be continued from the December number of *Shakspeariana*. "Browning's Poetic Form," a seminar (Johns Hopkins) lecture, by Professor A. H. Smyth; "Shakspeare's Verses in Chester's Love's Martyr," by Professor William T. Harris of the Concord School of Philosophy; "French and English Literature of Elizabeth's Day," by Professor M. W. Easton; and other contributions by Professor Hiram Corson of the Cornell University, Dr. H. L. Wayland, Michel N. Damiralis of Athens, Talcott Williams, and others, — are promised.

— D. C. Heath & Co. will put on the market shortly a series of games and charts for home and school use, based on the most approved principles of kindergarten training, prepared by Mme. Warwedel, the distinguished kindergartner of San Francisco, formerly of Washington. They have also nearly ready Scott's "Lay of the Last Minstrel," edited and annotated by T. E. Wetherell.

— G. P. Putnam's Sons will publish at once "The Pocket Gazetteer of the World," a dictionary of general geography, edited by J. G. Bartholomew, uniform with the "Pocket Atlas;" "The Nursery Lesson-Book," a guide for mothers in teaching young children, with illustrations in outline and a selection of songs set to music, by Philip G. Hubert, jun.; "Principles of Procedure in Deliberative Bodies," by George Glover Crocker; and three volumes of poetry, — "The Rose of Flame, and other Poems," by A. R. Aldrich; "Idyls of the Golden Shore," by H. Maxwell; "Mastor, a Drama," by John Ruse Larus.

— Charles C. Soule has just published a volume entitled "The Australian Ballot System, as embodied in the Legislation of Australia, Europe, and the United States," — a compilation of the ballot acts of South Australia, Queensland, Great Britain, Belgium, Kentucky, New York, and Massachusetts, with portions of the same of Tasmania, New Zealand, West Australia, Victoria, New South Wales, Dominion of Canada, Ontario, Quebec, Luxemborg, Italy, and other countries, with an historical introduction and cuts and diagrams.

— A prize of fifty dollars is offered by *The Academy* for the best essay on "English in Secondary Schools." The increased prominence of English in school programmes, and the lack of any generally accepted plan or system of work, have prompted the editor of *The Academy* to offer this special inducement to those who have devoted thought to the teaching of English, and who have definite ideas of the method of such teaching. The essays may be upon the teaching of English literature, methods of grammatical study, composition work or rhetoric, etc., but no weight will be attached to arguments in favor of teaching English. Contestants must confine themselves simply to practical exposition of results sought, and of the means of attaining these results in the schoolroom. While

literary merit will not be disregarded, the decision of the judges will rest mainly on the practical help afforded to teachers by the article. The competition is open to all persons, without regard to age, sex, color, or previous condition of servitude. The following are the conditions: No paper is to exceed in length 5,000 words; the paper awarded first prize by the committee shall become the property of *The Academy*; any papers of special merit, which may receive honorable mention, shall also become the property of *The Academy*; papers must be legibly written, so as to be published without copying, must be signed with a fictitious name (the real one being enclosed in a sealed envelope), and must be received at the office of *The Academy* on or before April 15, 1889. Manuscripts not receiving prize or honorable mention will be returned if stamps are enclosed. The names of the committee of award will be published. If further information is desired, address *The Academy*, Syracuse, N. Y.

— Dr. J. M. Toner of Washington has just brought out, in a handsome brochure, "Washington's Rules of Civility and Decent Behavior," found among the early writings of the first President, and now published in full, from the original text. They make thirty-four pages, and are believed by Dr. Toner to be an original compilation made when the compiler was only thirteen years old.

— Messrs. Belford, Clarke, & Co. will remove to new quarters Nos. 18-22 E. 18th Street, New York, about the 1st of February.

— We have received the third volume of the "Transactions and Proceedings of the Modern Language Association of America," being an account of the meeting held in Philadelphia in December, 1887, with the papers there read. The different essays, fifteen in number, are on a great variety of topics, but we can only notice a few of them. Some, indeed, are so technical that but few persons can enjoy or even understand them; while one or two were read only in part, and some that were read are not yet published. Of those before us, one of the most generally interesting is the opening one, by Mr. James MacAlister, on "The Study of Modern Literature in the Education of our Time." The author takes extreme ground in favor of modern literature as against the ancient, holding that "the literatures of the modern world are entitled to the first place in the intellectual culture of our time, and should therefore be made the chief instruments of literary training in the schools." Of course, the general sentiment of the meeting was with him in this opinion; but lovers of the classics will perhaps think that the question cannot be so summarily disposed of. Another paper of general interest is that of Professor Kroeh, on "Methods of Teaching Foreign Languages." The author reviews the various methods that have been employed, and pronounces in favor of the "natural" or conversational method; but, in the course of the discussion that followed, Professor Leidensticker suggested, that, though the "natural" method was best for giving a speaking knowledge of a foreign tongue, the grammar and reading were better for imparting a reading knowledge of it. Other papers read were on "The Style of Anglo-Saxon Poetry," on "Lord Macaulay's English," and other literary themes; and others still, on strictly philological subjects, such as "The Origin of the Teutonic Weak Preterite;" but these we can only allude to. There were also some essays with a distinctly local flavor; in particular, one by Professor Fortier on "Louisiana Folk-Lore," and another by Professor Primer on "Charleston Provincialisms;" both of which will be interesting not only to philologists, but to many others. It seemed to be the sentiment of the members present that the study of such local themes is specially incumbent on American philologists, the more so because local and dialectal peculiarities are fast disappearing under the influence of the common schools. The essays as a whole betray two distinct tenden-

cies, — the philological and the literary; or, in other words, the scientific and the æsthetic; and in some of the discussions that followed the reading of each paper these two tendencies came into collision. There seems, however, to have been great harmony of feeling at the meeting, notwithstanding many divergences in views. We are glad to add that the association passed a resolution in favor of repealing the tariff on foreign books; and we should be happy to record a similar act on the part of Congress.

— Miss Dora Wheeler, the well-known decorative artist, has given much of her spare time during the past two or three years to painting, either in pastel or oils, a series of portraits of authors here and abroad, many of whom are numbered among her personal friends. Unfortunately several of those of English authors who had given her sittings during her stay in London, in 1886, including Mrs. Thackeray Ritchie, Mr. Walter Besant, Mr. Thomas Hardy, and Mr. Austin Dobson, whose further acquaintance the American public is always glad to make, were lost in transit. Since that time her sitters have been exclusively American authors; and she has finished, or nearly finished, portraits of Mrs. Stowe, Mrs. Burnett, Mr. Lowell, "Mark Twain," Mr. Warner, Mr. Howells, Mr. Aldrich, Mr. Stockton, Mr. Burroughs, Walt Whitman, and others. The interesting announcement is made that these portraits will be given as frontispieces through the year for *The Literary News*, New York. Mrs. Stowe is portrayed in the January number, and Mrs. Burnett will be given in that for February.

— Ensign Hayden's nautical monograph No. 5, just published by the Hydrographic Office, is a graphic and picturesque report of the famous March blizzard. It is illustrated with four maps showing the advance and culmination of that extraordinary atmospheric convulsion.

— Mr. von Lindheim, an Austrian engineer, has compiled the statistics of street railroads in Europe. The development of such roads dates back not more than fifteen or twenty years. In England, France, Germany, Belgium, Holland, Austria, and Switzerland there are 221 cities having street-railroads. Among these, 118 are in England, 43 in Germany, and 23 in France, there being no city of less than twenty thousand inhabitants having such roads, while in the United States they are found in cities of not more than one thousand inhabitants. In Europe there existed in 1886-87 4,330 miles of street-railroads, while the United States had 5,932 miles. England had 883 miles on which 416,518,423 passengers were carried. In Germany 245,657,503 passengers were carried on 523 miles of road. In England 472,356 passengers were carried over each mile; in Germany, 468,874; in France, 545,815. There were 3,345 street-cars in Germany, 3,494 in England, and 2,780 in France, against 22,940 in the United States. In the latter, 92,203 horses, 12,217 mules, and 248 locomotives were in use on street-roads. Of considerable interest is the comparison of distance travelled each day by the horses. In Berlin a horse gives an average of 16.1 miles; in Posen, even as much as 16.7 miles; in Vienna, 14.5 miles; in Paris, 9.9 miles; and in Hamburg, 13.7 miles. The use of mechanical motors in place of horses is steadily increasing. It is particularly desirable in those places where the daily variations of traffic are considerable. In Berlin, for instance, the Sunday and holiday traffic is 27 per cent of the whole, and in Vienna even amounts to 34 per cent, while on Wednesday the street-cars are very little used. Mr. von Lindheim is a strong advocate of the use of electric traction in street-railroads, and states that in Europe the cost of horse-traction is 1.47 if that of electric traction is assumed as 1.

— Ticknor & Co. announce among their January books, "Steadfast," by Rose Terry Cooke; "Great Captains," by Col. Theodore Ayrault Dodge, U.S.A., — a series of six lectures delivered before

THE MOST PRACTICAL AND POPULAR OF THE MANY EXCELLENT TEXT-BOOKS RECENTLY PUBLISHED ON THIS SUBJECT.

Published less than one year ago, and already adopted for use in a large number of the leading High Schools, Normal Schools, Seminaries, Academies, etc., of the country.

MOWRY'S STUDIES IN CIVIL GOVERNMENT.

INTRODUCTORY PRICE, 94 CENTS.

SILVER, BURDETT & CO. Publishers, 50 Bromfield St., Boston.

NEW YORK: 740 & 742 Broadway.

CHICAGO: 122 & 124 Wabash Ave.

"Mowry's 'Studies in Civil Government' is the best book yet on the subject," A. S. Roe, *Principal of High School, Worcester, Mass.*

"A sample copy will be mailed to any teacher for examination on receipt of Introductory Price (94 cents). Examine Mowry's 'Studies in Civil Government,' before beginning with another class.

the Lowell Institute, Boston, in 1889, devoted to Alexander, Hannibal, Cæsar, Gustavus Adolphus, Frederick, Napoleon, and the record of their achievements and the analysis of what each of them contributed to military science; "Ancient and Modern Light-Houses," by Major D. P. Heap, Corps of Engineers, U.S.A.; a new edition of "Discourses on Architecture," by E.-E. Viollet-Le-Duc, richly and copiously illustrated with hundreds of steel engravings and woodcuts, translated from the French by Benjamin Bucknall; a new and cheaper edition of "A Hand-Book of Christian Symbols and Stories of the Saints, as illustrated in Art," by Clara Erskine Clement and Katherine E. Conway; and "His Two Wives," a novel, by Mary Clemmer, being No. 50 of Ticknor's Paper Series.

LETTERS TO THE EDITOR.

*Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith.

Twenty copies of the number containing his communication will be furnished free to any correspondent on request.

The editor will be glad to publish any queries consonant with the character of the journal.

Dew-Point and Predictions of Weather.

ONE of the most serious drawbacks to a discussion and utilization of humidity records has been the lack of proper observational methods, and also of tables of reduction. As late as 1884 we find in Guyot two distinct tables for reducing observations with the psychrometer (the usual instrument for determining humidity) which give results differing by more than sixty degrees at extreme dryness. Perhaps nothing can indicate better the hopelessness, as late as 1887, of nearly all attempts at solving the problem of the relation between the dry and wet thermometers and the dew-point, than the announced determination of the meteorological committee to omit a table for the psychrometer from their compendium of tables for international use. It will be generally admitted that such a table is the most important and most needed of any in meteorology. The most serious difficulty in nearly all investigations has been a lack of ventilation of the psychrometer.

In September, 1883, the sling psychrometer, which combines all the admirable qualities of perfect ventilation and accuracy, great speed of action, and extreme portability, was adopted in this country.¹

With this the true relation between the quantities mentioned above was determined in 1884, and published in February, 1885; and this has been used in the latest tables, leaving nothing now to be desired except observations to check the formula at extreme dryness, such as does not occur east of the Rockies.

I propose to discuss a few recent observations with the sling psychrometer. It might be a question as to the best form in which to study the moisture of the air. The relative humidity, the difference between the dew-point and air temperature, the dew-point itself, the absolute humidity, and the vapor pressure, have all had advocates. It may be remarked that the second of these, being a deduction from two quantities which are often rapidly varying in opposite directions, seems a little uncertain. The fourth and fifth are similar to the third.

The following propositions regarding the dew-point are set forth: 1. The diurnal change in air temperature does not affect the dew-point; 2. The temperature change from day to day does not change the dew-point; 3. The air temperature is generally very near the dew-point at sunrise, and farthest from it at 2 or 3 P.M.; 4. The air temperature in its fluctuations from day to day follows the dew-point; 5. Direction and velocity of the wind do not in general affect the dew-point; 6. The same may be said of fluctuations in air-pressure; 7. The most marked rise in the dew-point occurs on the approach of a storm having an abundance of rain and during rain itself (the time of beginning and ending of rain cannot be foretold from the dew-point); 8. The most marked fall in the dew-point is caused by the advance of a high area, as was to be expected; 9. The most marked feature of the dew-point is its constancy, though at times it has a range in several days far greater than the air temperature, yet it quickly recovers from a fall

¹ My attention has just been called to the use of a sling psychrometer by Espy in Philadelphia in 1834. His results, which were not entirely satisfactory, were far ahead of his time, and till quite recently exceeded in accuracy all others since. As is so often the case, they seem to have attracted little or no attention.

or rise to a normal position, depending on the season and other general causes; 10. The dew-point is the same in all parts of a quite extended region.

The fourth of these is one of the more important, and seems to follow from the third. We have usually been taught that the air temperature on a clear night will continue to fall till the dew-point is reached, when there will be condensation of moisture, and liberation of latent heat, which will prevent the further fall in temperature; but it will be found, that, except after a long rain and in a fog, the air temperature never reaches the dew-point. Very often on clear nights the latter falls, and draws the former after it. If this proposition can be established, there may be a chance to predict changes in air temperature from the dew-point, though they are very close together.

On many accounts the seventh proposition is the most interesting of all. Does the atmosphere in this case gradually sink down? This usually would increase the dryness. The wind does not appear to carry the moisture, for this steady rise occurs in a calm. Moreover, the direction of the wind, as coming from the earth's surface, makes little or no difference. It is very evident that the dew-point cannot be used in predicting rain. Under the eighth proposition it should be noted that the fall in the dew-point ceases in a few hours, and long before the pressure has reached a maximum. The figures from which these propositions arise will shortly be published elsewhere. It would be gratifying if others are stimulated to make similar research.

H. A. HAZEN.

Washington, Jan. 16.

Horns of the Prong-Buck (*Antilocapra*).

THE other evening, while reading an article on the *Artiodactyla*, by Professor Cope, in the *American Naturalist* for December, 1888, I was much surprised at finding the following note: "Antilocapra is sometimes separated from the Bovidæ as the type of a family, because it is said to sometimes shed its horn-sheath. This character, *were it really normal*, has no significance sufficient for the establishment of a family division" (*Italics mine*).

This doubt as to the shedding of the horn-sheath was so entirely foreign to what I had been led to believe, both by observation and reading, that I took the pains to look over what little literature I possess touching the subject; and, finding it so uniformly in favor of the shedding theory, I write, asking if your readers can give any additional facts in the case.

Owen (*Anatomy of Vertebrates*, London, 1868, vol. iii. pp. 626, 627) gives a description of the shedding of the horns, and growth of new ones, noticed by Mr. Bartlett in the Zoological Gardens of London in 1865; also notes of Dr. Canfield at Monterey, Cal., from 1855 to 1857, on a young male in captivity. Dr. Canfield is also quoted: "In the months of December and January I have never killed a buck with large horns; and at that time of the year all the bucks appear to be young ones, because their horns are so small; whereas in the spring and summer months almost all the bucks appear to be old ones, for their horns are then large and noticeable." Dr. Canfield also states that "in the summer months the line of demarcation between the horn and skin from which it grows is very apparent and abrupt; whereas in winter there is no demarcation, the horn being very soft at its base, and passing insensibly into cuticular tissues, and the horny substance being covered thinly with hair."

Gill (*Arrangement of the Families of Mammals*, Washington, 1872, p. 72) says of *Antilocapridæ*: "Horns deciduous, peculiar to the rutting-season (in both sexes), developed as pseudocorneous sheaths, with agglutinated hairs on osseous cores originating from the frontal bones." Gray (*Hand-List of the Edentata, Thick-skinned, and Ruminant Mammals in the British Museum*, London, 1873, p. 135) evidently believes in this shedding, because he places *Antilocapra* under a separate sub-order, *Dicranocera*, instead of merely a separate family. Mivart (*Lessons in Elementary Anatomy*, London, 1883, pp. 245, 246), on ederonic appendages, says, "and only in an anomalous form, the prong-buck (*Antilocapra*), are these horny structures shed at intervals;" Huxley (*A Manual of the Anatomy of Vertebrate Animals*, New York, 1883, p. 327), "But in the remarkable prong-horned antelope of North America (*Antilocapra*) the horny sheath is annually shed,

and replaced by a newly formed one." Caton (*The Antelope and Deer of America*, 2d ed., New York, 1881 [?]) gives a lengthy description of the shedding process as observed by him upon antelope in captivity; also quotes Audubon and Bachman (*Quadrupeds of America*) as saying, "It was supposed by the hunters of Fort Union that the prong-horned antelope dropped its horns,"—a supposition that these naturalists thought they had disproved by merely showing that it had an osseous horn-core. E. R. Alston (*Biologia Centrali-Americana*, 1879-82, p. 112, article "Mammalia") says, "Although the fact that the prong-buck sheds its horns annually was long well known to hunters and backwoodsman, and had been noted by one or two writers, yet it was generally disbelieved or ignored by zoölogists; and Mr. Bartlett, the observant superintendent of the Zoological Society's Gardens, was the first to demonstrate its truth and insist on its importance." Flower (*Encyclopædia Britannica*, 9th ed., p. 431, article "Mammalia") says, "The only existing species [of the *Bovidae*] in which such a process [shedding] occurs regularly and periodically is the American prong-buck (*Antilocapra*), in which the horns also differ from all others in being bifurcated."

This evidence resolves itself into three separate cases of direct observation on animals in captivity,—the statement by Audubon and Bachman of the belief of the hunters of Fort Union; and the indefinite statement of Mr. Alston, that "the fact that the prong-buck sheds its horns annually was long well known to hunters and backwoodsman."

My own observations are as follows. I have several times handled skins of this animal from the Western plains, from which the horn-sheath could easily be drawn, exposing to view a partially formed horn beneath. These, I have every reason to believe, were wild animals. I think, at the least, I have examined six or eight such cases; also I have noticed many cases in which the horn-sheath insensibly graded into skin, and was covered with hair for a considerable distance from its base, and many other cases where the demarcation was sharply drawn. Unfortunately I cannot recall at what seasons of the year these animals were killed. Again: in two or three cases have I known of taxidermists, uninformed that the phenomenon was known, coming to an independent conclusion that the antelope sheds its horns.

Now, let us see what the evidence amounts to. The generally accepted belief that confinement effects moultings must be taken into account; but, as far as I am aware, there is nothing in this evidence that would lend any support whatever to the idea that it could produce such a remarkable change as that of a permanently horned *Cavicornia* changing to a deciduous one. However, those antelope kept by Dr. Canfield and Judge Caton can hardly be strictly classed as animals in confinement. That of Dr. Canfield used to go hunting with him as far as twelve miles from home, we are told, and "hunted coyotes with the dogs at night;" while those of Judge Caton had the run of a large park. Neither can a change of climate or natural food be called in to account for this moult as described by Dr. Canfield, for his buck was living in its native habitat.

The opinion of the hunters of Fort Union is of considerable value. While hunters, Indians, etc., are not good at distinguishing species, yet habits, when well marked, are usually much more familiar to them as a class than to naturalists.

My own observations on prepared skins also point very strongly toward the same conclusion. In no manner did these indicate an abnormal physical state. Those observed in the United States in captivity evidently were healthy; and so good an observer as Mr. Bartlett would hardly have failed to have stated the fact if the specimen under his care was in poor health. That bucks killed in December and January all have short horns, grading insensibly into skin, and with base covered with hair, while those killed in the spring and summer months almost all have large horns, definitely marked off from the skin, can, I think, be explained in no other way than by an annual moult. That such is the almost universal belief of naturalists, my citations tend to show.

As the point is one of considerable interest, I have ventured to take up so much of your space, hoping thereby to call out some original observations from your readers. HENRY L. WARD.

Tacubaya, D.F., Mex., Jan. 10.

Felspar, or Feldspar?

I HAVE read with interest the recent notes in *Science*, Nos. 305, 306, and 309, on the orthography of "felspar" or "feldspar."

Whether the error consists in the omission or in the insertion of the *d*, seems doubtful. But apart from "national prejudice" in the matter,—which, if it exists elsewhere than in the imagination of your correspondent, "J. D. D.," is certainly to be deprecated,—there are, it seems to me, good reasons for defending and adopting the British custom of spelling the word. These are based on probability, common sense, and, last, though not least, appropriateness.

It may, I think, if there is no proof to the contrary, be admitted that the name was originally given by a miner, or a mineralogist, and not by an agriculturist; and, if so, then it is in the highest degree improbable that either the miner or the mineralogist would associate this particular substance with the fields, with which it has no obvious connection, and it is in an equal degree probable that he would associate it with the rocks of which it is one of the chief constituents. In any case, the British custom of referring it to *fels*, or *felsen* ("a rock," "rockspär") is both sensible and appropriate, neither of which can be said of its reference to *feld* or *felt* ("a field," "feldspär").

On these considerations alone, and not because of "national prejudice," or even custom, I consider it advisable to adhere to the spelling adopted by nearly all English geologists until some better reason than mere assertion, or the custom elsewhere, is advanced for not doing so.

ALFRED R. C. SELWYN.

Ottawa, Can., Jan. 14.

The Soaring of Birds.

PROFESSOR PICKERING may possibly have the correct explanation of the soaring of birds; and, if so, will he be kind enough to explain it more strongly, so that the explanation may have the force of a demonstration in geometry? As it now stands, there appears to be a fallacy somewhere.

If the bird is acted on by two forces, *AB* and *AD*, the resultant force would carry him to *C*; and he could by no means get to *G* except by the action of a third force, which might be represented by a line drawn from *C* to *G*. Professor Pickering makes no mention of any such third force, but without it how could the bird get to *G*?

WM. KENT.

Passaic, N.J., Jan. 12.

The Color of Katydid.

I OBSERVE in *Science* of Jan. 11 mention of a pink katydid found by L. N. Johnson, Evanston, Ill. A large female specimen was found on my place at Wood's Holl, Mass., as early as 1874, and sent to Professor Packard. Two others have been found at the same place, so that it would seem to be a defined species.

Insurance.

DELAY IS DANGEROUS.

We call attention to the new form of Accident (indemnity) Insurance policies, which are written by the Merchant's Casualty Insurance Association, at Park Row, New York City, John S. Purdy, Secretary. These policies cover weekly allowances of from \$10 to \$25, according to occupation, at a cost of only \$6 a year exclusive of the cost to join, which is \$5 payable once only. The public, as a rule, carry life insurance, and the ordinary accident policies issued by companies, paying a sum in case of death, is not so desirable as one of these indemnity policies in case of accidents, which are so plentiful in this fast age with its railroad horrors, fast driving, electric wires and other countless forms of dangero to which the public is constantly exposed. The fact of the Association having no unpaid claims, and its having just passed an examination by the Insurance Department of New York State, shows that the management is liberal with its policy-holders and conservative in its action. The Association also desires to secure energetic Agents in every village and town, to whom territory and favorable terms will be given.

ONE LANGUAGE FOR THE WHOLE WORLD.

WORLD-ENGLISH :

THE UNIVERSAL LANGUAGE. 25 CENTS.

EVERY one has heard of the butcher who, after a long search for his knife, at last found it in his mouth : so speakers of English have been seeking for a universal language, when, lo ! it is in their mouths. The intelligibility of English words has been obscured by a dense mist of letters. This is now dispersed by A. Melville Bell, who has already won a world-wide reputation through his invention of "Visible Speech," the great boon to deaf-mutes. Professor Bell calls this new discovery of his "World-English," and the result is a language which cannot fail to meet with acceptance, and at once supersede the supposed necessity for "Volapük," or any other artificial language. No language could be invented for international use that would surpass English in grammatical simplicity, and in general fitness to become the tongue of the world. It is already the mother-tongue of increasing millions in both hemispheres, and some knowledge of the language is demanded by all educated populations on the globe. Social and commercial necessities require that the acquisition of this knowledge shall be facilitated, and it is believed that Professor Bell's invention has removed the last impediment to English becoming the universal language, for which vague desires have long been entertained, although hitherto only futile efforts have been made.

Ex-President Andrew D. White, of Cornell University, says: "I believe that the highest interests of Christian civilization and of humanity would be served by its adoption. China and Japan would be made English-speaking peoples within fifty years, and so brought within the range of Christianizing and civilizing ideas, in the largest sense. All existing missionary work is trivial as compared with this. For your system would throw wide open those vast countries, as, indeed, all the countries of the world, to the whole current of English and American thought."

For Diffusion of English throughout the World

AS
THE UNIVERSAL LANGUAGE

This "Hand-Book of World-English" is the Complete, Simple, and Efficient Medium.

FOREIGNERS

Will Acquire, by Means of this Hand-Book, a
PERFECT PRONUNCIATION OF ENGLISH.
For Primary School Pupils and Illiterate Adults

World-English is a Royal Road to Reading.

To Teachers of English and Modern Languages

This Hand-Book will be of Primary Importance as a Phonetic Directory.

DEFECTS OF SPEECH

Will be Readily Corrected by Means of the Articulate Directions in this Hand-Book.

HAND-BOOK OF WORLD-ENGLISH,

25 CENTS.

The plan of this little book is altogether new. Letters and sounds are so associated, in all the exercises, that from the mere knowledge of letters a learner cannot fail to pronounce words with certainty. English reading will thus be easily acquired, whether by natives or foreigners, children or adults.

The general resemblance of World-English to Literary English is such that any reader of the latter deciphers the former at sight, or, at most, after a few minutes' study of the new letters. A like result may be anticipated for those who shall learn to read from World-English. They will transfer their power of reading to the literary form of the language, almost without effort. The orthographic aspect of words will, besides, be so fixed in the eye, by contrast, that spelling will be remembered as — what it really is — a pictorial association with words.

No special training is required to qualify teachers for using this book. The subject can even be successfully introduced in the kindergarten and the nursery. This phonetic mode of initiation in reading cannot be too strongly urged on the attention of School Boards on both sides of the Atlantic.

The ordinary orthography of each word is interlined with the World-English version throughout the Exercises and Readings.

So set down, our tongue is the best for the world to unite upon.—*Brooklyn Eagle.*

The idea of Mr. Bell has much to recommend it, and the presentation is charmingly clear.—*American, Phila.*

The result is a language which cannot fail to meet with acceptance.—*Boston Transcript.*

Has the merit of great ingenuity.—*Railway Age.*

His treatise, as a study of English orthoepy, condenses the result of much thought and experience in small compass.—*The Critic.*

World-English deserves the careful consideration of all serious scholars.—*Modern Language Notes.*

World-English is the English language unburdened of its chaotic spelling.—*Popular Science Monthly.*

We commend it to the attention of teachers.—*Ottawa Globe.*

"World-English" and "Hand-Book of World-English" can be had of all booksellers, or will be sent for 50 cents, post free, by the publisher,

N. D. C. HODGES, 47 Lafayette Place, New York.

Hon. ALBERT H. HORTON (Chief Justice, Kansas Supreme Court), Topeka, Kan., Pres't.

7% Guaranteed Farm Mortgages 7%

The Guaranty Investment Company makes loans upon fertile farms in the choicest portions of Kansas and Nebraska and has adopted the policy of sending a Committee of its Investors each year to examine its loans and methods of business.

The Committee this year consisted of PROF. A. H. BERLIN, Principal of the High School Montrose, Pa., and MAJ. THEODORE L. POOLE, Ex-U. S. Pension Agent, Syracuse, N. Y. Both of these gentlemen are persons of the highest character and have the confidence of the Communities in which they reside.

The Committee has recently returned and has made a very interesting Report upon the general development of Kansas and Nebraska as well as the business of the Company. The Company will be glad to send this Report to any address.

The following names are taken from the long list of Investors in our Mortgages:

Address for Report and Monthly Bulletin

HENRY A. RILEY, General Eastern Manager, 191 Broadway, N.Y.

A Useful and Handsome Present.

Prices Reduced for the Holidays.

The *Hulin* Fountain Pen

Warranted 14 karat gold and to give perfect satisfaction—is pronounced by hundreds of pleased customers to be the best fountain pen in the market because it is always ready. Writes freely and never gets out of order.

Sent by mail prepaid for \$1.50, \$2.00 and \$2.50 each, according to size selected.

These are special prices for the holidays, and this offer should be availed of by all who write.

JOHN S. HULIN,
Mfg Stationer and Steam Printer.

Wedding Invitations and Visiting
Cards Engraved to Order.

OIL-BURNING STEAM-ENGINES.

THE engine known as "The Shipman," an illustration of which accompanies this article, is an automatic steam-engine and boiler complete, using kerosene-oil of a low test for fuel, and is designed for all users of a moderate amount of power. Its essential points are, that it is so thoroughly automatic in fuel, water-supply, and speed, that, when steam has been raised, little if any further atten-

tion is required beyond that of opening or closing the throttle-valve when the engine is started or stopped. The fire is formed by a mixture in proper proportions of steam and oil. This is fed through one or more atomizers, according to the size of the boiler. A supply of steam from the boiler passing through these atomizers carries with it into the fire-box, in a fine spray, just the amount of oil necessary to generate steam for the work being done by the engine. As the oil enters the fire-box, it is ignited by a torch, and the combustion is so perfect that there is little or no smoke; so the full value of the heating qualities of the oil is obtained.

If the engine is stopped, the fire is entirely put out by the diaphragm; but upon starting again, the fire at once relights itself, the

FOUR-HORSE-POWER SHIPMAN ENGINE

tion is required beyond that of opening or closing the throttle-valve when the engine is started or stopped.

In burning the oil, no wicks are used, and there is nothing to gum up or clog. The fire is formed by a mixture in proper proportions of steam and oil. This is fed through one or more atomizers, according to the size of the boiler. A supply of steam from the boiler passing through these atomizers carries with it into the fire-box, in a fine spray, just the amount of oil necessary to generate steam for the work being done by the engine. As the oil enters the fire-box, it is ignited by a torch, and the combustion is so perfect that there is little or no smoke; so the full value of the heating qualities of the oil is obtained.

The amount of steam and oil used by the atomizers is controlled by a perfectly automatic diaphragm-valve, located in the steam-pipe between them and the boiler. Through this diaphragm, the mechanism of which is simple, and to which easy access can

be had, passes the steam on its way to the atomizers; and, as the pressure of the steam in it becomes greater or less than the tension of the spring which governs it, a valve attached to the diaphragm-plate is made to close or open, and thus regulates not only the amount of steam and oil being consumed, but also the pressure in the boiler. In this manner the fire is increased or decreased, according to the load on the engine, and the steam-pressure is kept constant. The height of the pressure to be carried is at the option of the user, and can be varied by him almost instantly.

If the engine is stopped, the fire is entirely put out by the diaphragm; but upon starting again, the fire at once relights itself, the

steam-pressure having been held, in the mean time, by the automatic action of the diaphragm, which will have allowed just enough oil to be burned to make up for the loss of steam by condensation. The supply of oil is stored in a tank placed at any convenient distance from the boiler, and is led to it by ordinary piping. The boiler consists of a hollow oblong back constructed of steel and thoroughly stay-bolted. Into one side of this back are screwed lap-welded wrought-iron tubes one and three-quarters inches in diameter, and thirteen inches in length. These tubes are closed at the outer end by a welded plug. This makes a very compact and quick-steaming boiler, gives large heating surface, and insures safety, it being almost impossible to explode one so that it will do harm. The boilers are tested by a hydraulic pressure of four hundred pounds. As a matter of record, steam can be raised on a four-horse-power boiler, from cold water to one hundred pounds pressure, in ten or twelve minutes.

The water-supply is by a plunger feed-pump, run direct from the engine-shaft, and is kept at a uniform level in the boiler by means of a float connected to a valve in the suction of pump. This float is in a chamber which is connected by piping to the top and bottom of the boiler, and rises or falls with the water. The movement is conveyed by levers to the valve in the pump, which it opens or closes as the water-level changes.

The engine is well built, and of the best material. The piston is solid, and has sectional packing-rings, each section overlapping the other, and being set out by independent springs. This, of course, makes a very tight and true-wearing ring.

The valve is of the piston type, and perfectly balanced.

The governor is an automatic cut-off, working direct from the shaft to the valve; and the speed is very finely regulated, no matter

The engines and boilers are now built on one or separate bases, of one, two, four, six, and eight horse-power, and the company have in process of construction compound and triple expansion engines of various sizes. For further information, address the Shipman Engine Company, 92 Pearl Street, Boston, Mass.

WATER FILTRATION AND AERATION.

THE rapid growth of the mill industries, and of the arts and manufactures in general throughout the country, bring more than ever prominently to the front the important questions of the purity of the water-supply, and the necessity of taking immediate and active measures to secure this greatly to be desired quality. Particularly is this the case in the southern section of the country, toward

NATIONAL FILTER PLANT AT CHATTANOOGA, TENN.

what the load. The shaft is of cast steel, very large, and having extra long bearings in babbitted boxes.

All wearing parts are of extra size, and adjusted for the taking-up of lost motion. Lubrication of the cylinder is by a sight-feed; and the slides and shaft-boxes, by the ordinary oil-cup. Oiling of the crank-pin is effected by a centrifugal oiler attached to the crank-disk.

From the above it can be seen that when steam has been raised, and a sufficient quantity of oil and water supplied, the engine requires no further attention.

The question is asked, How are the fires operated when there is only cold water in the boiler? For this purpose a hand air-pump, attached to the boiler, is provided. A few strokes of this pump will start the fires, and it is only necessary to pump slowly for seven or eight minutes to raise enough steam to keep them going. As soon as steam is made, all work with the air-pump ceases, and, as before stated, one hundred pounds can be raised in from ten to twelve minutes. As regards the other advantages of "The Shipman," it can be said that it is compact, light, and durable, and entirely dispenses with the services of a skilled engineer.

which the attention of capitalists throughout the world is being more and more attracted. The more important features of health and cleanliness render it an imperative duty to prepare for the rapidly increasing population of our cities by taking judicious measures to secure to every community that system which, having simplicity and durability to recommend it, will, while being economical, insure a sufficient supply of pure water for individual use as well as for the factories and mills. Our country is blessed with a plentiful water-supply in almost every section, and the very fact of the abundance of this supply necessitates the precautions above referred to; as so large an amount of matter is carried in suspension in most of our large rivers, that some system of filtration must be resorted to. Some of the features that tend toward the perfecting of apparatus for this purpose are the ability to maintain the necessary "head or pressure," simplicity of construction, durability, quickness and thoroughness in cleansing, economy in water to accomplish this cleansing, cheapness, strength to withstand any desired pressure, and capacity to supply the maximum amount of clear water required for the purpose in view. The National Water

Purifying Company of New York have in their apparatus combined many, if not all, of these requirements; and an extensive plant installed by them at Chattanooga, Tenn., gives conclusive proof that scientific principles have entered into the construction of the plant, which seems to have well stood the crucial test of actual practice. The rapidity and thoroughness with which these filters can be cleaned, and the small expenditure of water required, are qualities in which this company excels, as they seem to have effectually solved the vexed question of surface washing. It has been found, from long experience, that most of the impurities taken from water, in the course of twenty-four hours lodge in the upper

in the boiler, necessitates a periodical stopping for its removal, ceases to be troublesome. It has been demonstrated beyond question that the thorough purification of drinking-water can be accomplished by combining aeration, precipitation, and filtration; and it is also reasonably claimed that the thorough aeration of water under pressure has the effect of destroying bacteria and plant-life that would be injurious to health. The aeration is accomplished by means of an air-compressor, whereby air is forced into the water under high pressure, thus producing a chemical action, which destroys the disease germs in the water, making it clear and sparkling. The process employed to attain this end by

SECTIONAL VIEW OF NATIONAL FILTER (250 GALLONS PER MINUTE).

six to ten inches of the sand-bed through which the water must pass before it leaves the filters, and that in their large machines, having a capacity of 250 gallons per minute of pure filtered water, this surface washing can be accomplished in four minutes, after which a reverse current up through the sand-bed breaks it up completely, and throws out all the finer particles of dirt. As the only labor required to accomplish this cleansing is the mere opening and closing of valves, the reverse current doing all the work, some idea of the extreme simplicity of the filter can be formed. By creating a feed of water free from those impurities which induce the formation of "scale" in boilers, a great economy of "fuel" is effected; the salts and other deleterious substances being deposited in the sand-bed of the filter, instead of passing into the boiler and shortening its period of usefulness by hastening corrosion, while the sediment that induces foaming, and which, gradually settling

the National Water Purifying Company is simple and inexpensive, and by it the amount of air forced into the water can be regulated to the exact requirements of the case. As a result, all odor in the mains, and vegetable growth, such as algæ, in the reservoirs, are prevented.

THE CULTIVATION AND UTILIZATION OF RAMIE IN THE UNITED STATES OF AMERICA.

IN his recent report on the Brussels Exhibition, Mr. Joseph Zervas draws attention to the importance of the cultivation of ramie. During the last thirty years, he says, numerous experiments have been made with a view to finding new plants yielding textile fibres. One of the most promising among these is the ramie, which is obtained from two plants, — *Bohmeria nivea*, yield-

ng white ramie; and *Bohmeria utilis s. tenacissima*, yielding green ramie. The fibre, which is also called "rhea" and "China grass," has been imported in considerable quantities into Europe, and extensive experiments have been carried on in regard to its utility.

Ramie is a perennial plant, the bark of which gives a textile fibre superior in tenacity and resistance to that of flax and hemp, while at the same time its length, fineness, clear white tint, and lustrous brilliancy, give it a great resemblance to silk. The amount of textile material obtained from a certain quantity of this plant is considerably larger than that obtained from an equal quantity of either flax or hemp.

Although in some respects inferior to silk, it can be used as an imitation of it; while it will undoubtedly supersede hemp, flax, and harl. Like cotton, it will have its centres of manufacture, and the peoples of the earth will be interested in the progress made in its use. The beauty of its products, the fineness and durability of tissue, more especially its clear tint, make it suitable to take the place of linen goods; and its easy manufacture will insure its rapidly gaining supremacy over other textile products.

The cultivation of ramie was introduced into Mexico by Mr. Benito Roelz de Santo Comspan; into the United States, by Mr. J. Bruckner of New Orleans; and into Belgium, by the Josephites of Melle, near Ghent. In Germany and Bohemia the first experiments were made with white ramie, as it was thought to be more advantageous, owing to its readier acclimatization to countries less warm than China or Japan, from which it had before been imported; but so far its cultivation, for reasons which will be shown later, has made but little progress. Recently machinery has been invented which makes its manufacture more successful; and since that time this industry has made rapid progress. Governments of several European nations are taking an active interest in the cultivation of this plant.

The utilization of ramie fibres is of great antiquity. Their virtues are recorded in the poems of Ramagana and of Kalidasa, who sing the praises of the stuffs made from ramie, which seems to have been grown at that time in the Himalaya Mountains. Pallas contends that the Chinese frequently deceived the Russians by selling them stuffs manufactured from ramie-thread (the wool alone being of real silk) as real Damask silk. We find in the annals of Nestor, of the year 904, that the sails of the Volga vessels were nearly all manufactured from ramie fibre.

Various kinds of nettles, or ramie, were cultivated in Russia, Siberia, Kamtchatka, and Japan. Dr. Boyle says that in 1810 the first tests of Sumatra ramie were made in India. In 1851 experiments were made in the spinneries of Leeds, which proved very encouraging. In 1868 the price of the raw fibre was £20 per ton at Calcutta, and £40 at London.

Although the cultivation and industry of ramie are still principally limited to the countries to which its growth is indigenous, the attention of every agricultural country, and of every textile manufacturer, should be drawn to its value with a view of determining as to the benefits to be derived from its introduction.

No country is better adapted for the introduction and cultivation of ramie than the United States, which, owing to its extensive territory, affords all possible conditions for cultivation as regards either soil or climate, and where the power of capital conduces so favorably to the development of enterprises.

It is not difficult to imagine the importance which this new industry may gain in the United States, when we consider that in 1887 the total importation of textile material (flax, hemp, jute, and other vegetable substances) from foreign countries into the United States amounted to about one hundred and twenty-three thousand tons, representing a money value of fourteen million dollars.

The exportation of vegetable fibres of every kind to the United States from the consular district of Brussels (Belgium) amounted, in 1880, to \$54,411.88; in 1881, \$58,307.68; in 1882, \$34,065.78; in 1883, \$41,989.20; in 1884, \$37,041.14; in 1885, \$51,004.56; in 1886, \$62,587.30; in 1887, \$39,245.92. The falling-off in the exportation of last year is due to the probable change in the tariff.

It has been inferred above, that, as a result of experiments made towards acclimatizing ramie in foreign countries, there has not been any extraordinary industrial success, although remarkable progress regarding our knowledge of the plant, and the best methods of

treating it, has been made. Even in the utilization of the fibre for spinning purposes, many difficulties were encountered until lately. The obstacles in the way of the cultivation of ramie arose principally from the fact that the plant itself, and the practical utility of it, were unknown; that statements regarding its use had been found erroneous, exaggerated, and untrustworthy.

No knowledge whatever of the soil suitable for its growth and cultivation, nor of the proper climate, was possessed. The culture of an inferior kind of ramie was introduced into northern countries, and its merits were so highly exaggerated that its partial failure prejudiced many of its warmest adherents. This species, the white ramie, is not nearly as good as the green.

Among the different kinds of ramie experimented upon with a view to their introduction into Europe and America, only these two species are accepted as being useful and suitable for acclimatization. The *Bohmeria nivea* (the white ramie), of Chinese origin, belongs to the temperate zone. The under part of its leaves is of a nacreous white color, with green veins, the leaves and stalks being very vigorous. The ripe stalk is of a red-brown blood color. Its fibre is greatly inferior to that of the green ramie, it is rougher to the touch, is not so full, and bears less resistance to tension. The stalks do not grow so high, and they have less tendency to run to seed. The plant also resists the cold better; for, while one has to be protected in severe weather, the other has not, and can be left in winter in a meagre soil. The *Bohmeria tenacissima* (green ramie) comes originally from an equatorial district, Java. Its fibres are very strong, and the plant is more hardy, and more prolific in fibrous textile, than the other.

The average height of the stalk of the green ramie is about five feet and a half to six feet, while that of the white ramie is of considerably less height, being about four feet and a half. In addition to this, the latter plant grows numerous side branches, which renders pruning more difficult. Accordingly, the product of the green ramie is shown to be superior to that of the white ramie.

It would seem, therefore, that it is a mere question of climate, which favors white ramie, though a recent cultivation of green ramie in Italy, in the province of Padua, shows it to have withstood a temperature of -9° C. or 16° F. In Algeria green ramie has been cultivated exclusively for some time.

Ramie can be raised from seed, from suckers, or from layers or pieces of roots. That reproduced by seed-plants requires too much care, and has a greater tendency to run wild. Suckers have various disadvantages: ten per cent die, and the others cannot withstand the cold. The simplest, surest, and most productive mode of reproduction is by pieces of roots, or cuttings of stalks stuck into the ground. This kind is more productive, fuller, is neater and more easily grown, and reaches maturity at an earlier period.

A comparison of the cultivation of the two species in Italy gives the following result as a fair sample of its produce. Ten thousand mother plants on one hectare gave for two cuttings, —

	Dry Stalks, Kilograms.	Pruned Fi- brous Textile, Kilograms.	Harl per 1,000 Kilograms Stalks.	Harl. Per Cent.
White ramie.....	6,000	1,930	172	17
Green ramie.....	8,000	1,600	199	20

The soil in which ramie should be planted should be light, sandy, well manured and cultured, naturally cool and moist. A good underground is indispensable, as the plant throws out its roots to a depth of from twelve to fourteen inches. It may be said, however, that it accommodates itself readily to almost any kind of soil, but the one indicated gives far superior results. If the soil be too rich, the plant thereby acquires a deleterious amount of ligneous material, which lessens the strength of the plant's fibres. The stalk becomes sappy, more difficult to prune, and hence inferior in quality. A too damp or marshy soil is injurious; although it has been experienced in different districts where it is grown, that a thick coat of mud of a sandy nature, the result of an inundation, has proved rather favorable instead of prejudicial in its effect. A

persistent drought gives a thin and sickly crop: therefore it will be found necessary, where the plant is grown under the influence of great heat, to facilitate the vegetation by frequent irrigations, according as the soil is more or less of an absorbing nature. At least two weeks previous to the cutting of the plant, the irrigations ought to be discontinued, to allow the stalks to gather sufficient strength, ripen, and dry sufficiently for use. In order to secure a good crop, and avoid fermentation of the stalk, it is preferable to cut in dry weather. The manner of planting is quite simple. In the soil already prepared, furrows at least three feet apart should be ploughed (similar to those made in planting potatoes). The plants are then placed in the furrows at three inches depth, so that they alternate with those of the next line. Each plant requires a square yard for its development. This space will be occupied by direct shoots or rhizomas from the end of the second year.

In the third year it will be necessary to thin the plants. In order to secure a free circulation of air, the soil should be carefully weeded during the first year of the plant's growth. In the second year it will be found unnecessary, the ramie overgrowing the weed. It is advisable in spring, or after the first cutting, to dig up a little of the soil about the roots. As the plant is perennial, the better the soil is prepared, the better will be the results. Quoting from the analysis of Dr. J. E. Tornidge, the composition of the fibre is as follows:—

Potash	32.37
Soda	16.33
Lime	8.50
Magnesia	5.39
Oxide of iron17
Chloride of iodium	9.13
Phosphorus	9.60
Sulphur	3.11
Carbon	8.90
Alumina and silica	6.60
	100.00

Ramie, like flax and hemp, exhausts the resources of the soil rapidly: therefore careful manuring is necessary. The above analysis may be a guide in selecting the fertilizer. In Europe only two cuttings a year can be depended upon; for, even by the use of liquid manure with irrigation, it has been ascertained that a third crop is extremely sickly and weak, even under the most favorable circumstances. In countries where the climate resembles that of regions to which the plant is indigenous, as many as five crops can be obtained if great care be given to its cultivation. The best time for gathering it is when a red-brown color is visible in the lower part of the stalk.

The stalks should be cut at about four inches from the ground, by a clean incision, to avoid damage. It is then necessary to dry them quickly in the sun; and they should be peeled within at least forty-eight hours, after which time peeling would be difficult.

If stored for winter use, it should be kept in a dry place. In the process of drying, the leaves should be stripped. If used for cattle-feeding, as is often the case, they should be given while still green. This, however, is an expensive proceeding. When the stalks are dried with the leaves remaining on them, they can be easily shaken off at the end of two days. They can be usefully employed in the manufacture of paper, or left on the ground, for which they form a good manure. The produce of the stalk is, as shown, dependent upon the climate and proper treatment. As no statistics have yet been made in countries where its growth is indigenous, it is necessary to make an estimate from the results obtained in countries less favorable to its growth: therefore the estimates are probably too low. In Italy, in the third year, when the plantation reached its definitive state, the produce of one hectare (2,471 acres) of ramie amounted to about 80,000 kilograms (1 kilogram = 2.2 pounds) green stalks, of which one-half is attributable to leaves. The first cutting gave 41,200 kilograms, the second 39,700 kilograms, green stalks, which together makes 80,900 kilograms. Deducting fifty per cent leaves, there remain 40,450 kilograms of green stalks, or 1,600 kilograms harl. Two thousand kilograms of harl have even been obtained, and 1,800 is not an exaggerated average, per hectare.

Labor, manure, rent, pruning-machines, and general expenses are of course to be counted; and, as such expenses would in

America be highly in excess of those in Italy, it could only be by practical trial and experiment that the cost of its cultivation in the United States could be ascertained. The results show, however, that the cultivation is extremely remunerative, and in the United States it would prove still more profitable.

The greatest difficulty yet experienced in the industry is that of properly peeling or decorticating the stalks. With a view of promoting this industry, the Indian Government, in 1870, offered a prize of £4,000 for the best machine manufactured to peel the raw fibre; subsequently a prize of £5,000 was offered in England for the same purpose; and quite recently an exhibition has been decided upon, to be opened on the 25th of September, by the minister of agriculture in Paris, for machines for the purpose of peeling ramie stalks. As in the case of all textile plants, the object is to separate the ligneous part from the herbaceous part; that is to say, the stalks from the bark. The ligneous part is used for manure only. The bark, on the contrary, contains the fibrous matter for the manufacture of harl. Its manufacture is possible in several ways. First, during the first two days after the cutting of the stalk, the viscous liquor which is found between the ligneous part of the stalk and the bark allows it to be peeled with facility. The Chinese and Indians simply employ their forefinger and thumb to peel the bark while in that state. This is of course primitive, and machines based on that principle have always been found unsatisfactory. Second, many inventors proceeded, as in the case of flax and hemp, by a kind of previous maceration called "retting;" but this also has proved unsatisfactory, on account of its speedy putrefaction, hemp being capable of greater saturation than ramie. Third, chemical operation has at all times proved prejudicial to ramie fibre, causing loss of weight and brilliancy of appearance. Fourth, other manufacturers constructed machines with a view to abandoning retting. These are constructed so as to peel the harl, and do the least possible injury to the textile qualities of the plant, and, by working the plant when dried, to completely disaggregate the fibre so as to render it of greater value. When working green, there is apt to be a great loss of fibre, as it is impossible to perfectly peel the stalk. The disaggregation is poor, the fibre leaving the machine in strips, which necessitates its being worked by chemical substances, to obtain the division of the thread: hence a machine working dry, with little loss, is of greater advantage.

Among the machines working green, that of the American, Mr. Berthel, gives a waste of more than one-half of the textile fibres. Requiring a force of two horse-power, it is able to work 150 kilograms (330 pounds) of dry harl per day, the price being \$500 for this machine. The machine built by Felix Roland, a French engineer, is somewhat better; but the waste still amounts to two-fifths of the whole. The machine of three-quarter horse-power works 150 kilograms of dry harl, and costs \$250; that of one horse-power works 200 kilograms (440 pounds) dry harl, and costs \$360. The machine of Messrs. Moermann-Laubuhr, Belgian engineers, which is really an old flax machine, requires a previous maceration of the plant, necessitating thereby inconveniences. It requires four horse-power to work 200 kilograms of harl per day, and its price is \$1,200. Among dry-stalk working machines is one manufactured originally for flax by Arthog, which works 100 kilograms (220 pounds) at two horse-power, and its price is \$800. Until recently (1875), the best machine originally built for flax was manufactured by Cardow & Son, and improved upon by Huet Lagache, for the treating of ramie; but the harl often rolled up around the cylinder, the brown epidermis was often left, and considerable loss ensued. The produce is 200 kilograms for four horse-power, the price being \$2,000. Felix Roland, who was mentioned above, also built a machine for working dry stalk. Little injury, as well as little loss, was experienced by the use of this machine. Of these machines he has three different sizes. No. 1 produces 60 to 70 kilograms (130 to 154 pounds) a day, worked by a man, the price being \$300; No. 2 produces 150 to 160 kilograms (330 to 352 pounds) a day, three-quarter horse-power, the price being \$440; No. 3 produces 200 to 250 kilograms (440 to 560 pounds) a day, one horse-power, price \$600.

Peeling expenses do not exceed three per cent by this system, wages being reckoned at \$1.25 per day. This machine was considered the best, as is shown by the fact of the minister of the

French Navy buying one for the colonies of Guinea, etc. Lately, however, in the Brussels Exhibition, the new stripping and peeling machine of Norbert de Landtsheer from Paris was exhibited, and it is the most simple, complete, and inexpensive machine yet used for the peeling of either dry or green stalks. Peeling is accomplished without crushing, and the threads are free from cuts. The dis-aggregation is perfect, and the machine is free from waste in either dry or green peelings. The daily product is: dry, 100 to 158 kilograms (220 to 330 pounds), a quarter to one horse-power; green, 100 to 200 kilograms (220 to 440 pounds), a quarter to one horse-power, price \$240. A machine run by hand-power produces 75 kilograms (165 pounds), price \$200.¹

On a large scale of cultivation, a corresponding series of machines built by Norbert de Landtsheer will be necessary. With this in view, and the value of these machines being established, there is no longer any doubt as to the success of its introduction into the United States, where the conditions of soil and climate are so favorable.

they birds or fish, have such a form, the larger end being the forward end in their movements. To maintain the shape under varying pressure, there are two air-tight conically shaped compartments, — one at each end of the balloon proper, — into which air or other gas may be forced, as occasion may require, to keep them distended.

The buoyant power it is proposed to make just sufficient to raise the ship; and if, on rising higher, the warmth of the sunlight or other cause should expand the balloon, some of the gas would be removed, and condensed, thus doing away with the clumsy make-shift now in vogue of throwing out ballast.

To start with, the balloon is supposed to be filled with just enough coal-gas to cause it to rise. As the balloon rises, a portion of this gas may be withdrawn and compressed, and another portion may be employed to drive the motor, and some part will escape. To replace this loss of buoyancy, there is a reservoir in the car containing a solidified gas, the composition of which Mr. Boisset still keeps a secret, but the basis of which is ammonia, from which

Throttle-valve for ammoniacal gas; 24. Wheel with air-sails.

It is not within the scope, nor is it the intention, of this article, to advise agriculturists to proceed to develop this industry on the strength of the information and statements contained in this report, but rather to draw the attention of the United States to the feasibility of its introduction into the country.

AN AIR-SHIP.

MR. LOUIS BOISSET, a retired officer of the French army, is now in this country, perfecting an air-ship, an invention of his, and seeking the protection of the United States patent laws.

Mr. Boisset has had some experience in recent years with the air-ships experimented upon by the French war department, the more or less successful voyages of which over the suburbs of Paris were recorded in *Science* in 1884. One trouble with these older forms Mr. Boisset believes to have been due to their symmetrical form, and he seeks to make the equilibrium of his balloon when in motion more stable by giving it, as shown in the figure, an ovoid form, following in this the dictum of Mr. Dupuis de Lome, — that in general, organisms destined for motion in water or air, be

¹ At aforesaid September Exhibition at Paris the decorticating machine of De Landtsheer was recognized to be the best.

a fresh supply of gas can at will be obtained, and introduced into the lower compartment (18) of the balloon.

Mr. Boisset believes that he has made improvements over any thing that has gone before, in the shape and rigging of the ship, in the gas-motor, and in the method of compensation by which the equilibrium of the ship may be maintained. Further, the dividing of the balloon into air-tight compartments is a novel feature, and allows of replacing the consumed coal-gas by the ammoniacal gas, whatever its composition may be, without mixing the two.

Mr. Boisset estimates that a vessel of his construction, capable of crossing the Atlantic, should have a gas-chamber (the balloon proper) 62 metres in length, and with a maximum diameter of 20.33 metres. The height from the top of the balloon to the flooring of the basket would measure 31 metres; and the length from the end of the propeller to the end of the rudder-sail, 82 metres. The weight of the ship, its provisions, crew of ten men, and passengers, the inventor would place at 6,000 kilograms.

AMONG the features of the issue of *Light, Heat, and Power* for Jan. 19, are four photographic plates, illustrating the recent gas-holder explosions at the works of the Citizens' Gaslight Company, Brooklyn, N.Y.

ELECTRICAL NEWS.

Hertz's Researches on Electrical Oscillations.

In reading Faraday's "Experimental Researches on Electricity," one finds many experiments described in which that philosopher attempted to show that some relation must exist between natural phenomena which had been considered as having no connection with one another. He tried to prove that gravitation could produce magnetic or electrical effects; and although he failed, yet at

FIG. 1.

FIG. 2.

the end of the research he expressed his belief that some connection existed, and would some day be discovered. But he did find that a magnetic field had an effect upon polarized light passing through it, and this discovery has been developed until Maxwell advanced the hypothesis that electrical vibrations may be propagated through space according to the same laws that govern the propagation of light, and with the same velocity; and now the theory of Maxwell has been experimentally verified by Hertz. The evidence in favor of Maxwell's theory, before Hertz published his work, lay principally in the facts that the equations of propagation of an electro-magnetic disturbance were practically those which have been deduced for light, and which have explained a number of the phenomena that take place. The velocity of such a disturbance is equal to a constant which can be determined electrically, and which agrees very well with the observed velocity of light; while a relation between the specific inductive capacity, determined electrically, and the index of refraction of a substance, agrees fairly well with that deduced from Maxwell's theory. Hertz has added to this evidence a proof—indirect, but fairly conclusive—that the "electrical displacements" in a dielectric, on which rests much of Maxwell's theory, really exist; that actual electro-magnetic waves are reflected and interfere with one another; and that the velocity of such waves is about what is calculated. We will describe Hertz's experiments as clearly and briefly as possible, referring those who desire a detailed description to Hertz's and De Funzelmann's papers.

In the first place, it was necessary to produce electrical oscillations of a very small period. Roughly, the period of a light-wave is 10^{-16} of a second, and we know of no way of producing electrical oscillations, on a conductor of finite size, of any thing near so rapid a period. When Hertz took the matter up, the most rapid oscillations that had been experimented upon were those caused by the discharge of a Leyden jar through a resistance, the period being about 10^{-6} of a second. Theoretically a much shorter period would be obtained with conducting-wires forming an open circuit, the ends having small knobs on them; and this is the form Hertz first experimented on, his object being to discover whether measurable oscillations were really produced. The period in this case should be some hundred millionths of a second, — 10^{-8} as compared with 10^{-16} for light. The general arrangement of the apparatus is shown in Fig. 1. Here *A* is a large induction-coil, with the wires *B* fastened to the terminals of the secondary circuit. The

coil Hertz used was a large one, 52 centimetres long by 20 centimetres in diameter, and it was run by six large Bunsen cells.

When the coil is working, there are sparks between the knobs *B*; and, when one of these sparks passes, we have the case of the discharge of conducting-wires forming an open circuit; and this will cause rapid oscillations along the wires, which will diminish in amplitude until they are re-enforced by another discharge. To observe these disturbances, Hertz arranged a circuit, shown in Fig. 1 at *M*. This was simply an open circuit of wire, with two adjustable knobs, 1 and 2. On connecting this "micrometer" circuit to one of the wires *B*, the connection being as shown in Fig. 1, sparks, sometimes several millimetres long, passed between 1 and 2.

The reason of this is, that the rapid and violent oscillations on *B* are transmitted to the knob 1, sometimes causing a high and sometimes a low potential at that point. Now, if it takes a finite time for this disturbance to travel around the circuit *M*, then there will be for a short time a considerable difference of potential between 1 and 2, and this causes the spark. With the connection to *M* made as in Fig. 2, the distances of *e* from 1 and 2 being equal, then the disturbance reaches these points at the same moment, and there is no difference of potential between them, and therefore no spark. This is what Hertz actually finds.

Some of the facts that Hertz obtained were these: In the first place, the effect in the micrometer circuit depends on the shape of the terminals *B* and on the nature of the spark: the material and size of the wire of the micrometer circuit has very little influence on the spark. If, when the contact is at *e* (Fig. 2), a conductor be joined to one of the knobs 1 or 2, then the spark re-appears.

This last, Hertz thinks, shows that the phenomenon cannot be due to single waves in the directions *ca* and *db* respectively, but must be due to a series of oscillations set up in the micrometer circuit; and the addition of a conductor to one of the knobs changes the period of vibration of that branch, the periods being determined by the product of the coefficients of self-induction into the capacities of the branches. The fact that the material of which the circuit is made has no effect on the spark, tends to show the same thing; namely, that the phenomena in the micrometer circuit are dependent upon self-inductions and capacities, that is, upon time-constants.

FIG. 3.

To further prove the oscillatory character of the discharge, Hertz used the arrangement of Fig. 3. Here the micrometer circuit was placed with one of its sides parallel to the wire *gh*, which was connected to one of the discharge wires *B*. The sparks at *M* were very feeble until a conductor, *C*, was attached to the free end, *h*, of the wire, when they increased to two millimetres. No effect was produced when *C* was attached at *g*. When the knobs at *B* were so far apart that no sparking took place, the sparks at *M* also disappeared, which showed that they were due to the sudden discharges, not to the charging current. While *C* was attached to *h*,

¹ Hertz's original papers are in Wiedemann's *Annalen*, 1888. Mr. G. W. de Funzelmann has given an excellent *résumé* of Hertz's work in the *London Electrician*, Nos. 539, 545, 547, 548.

and the knobs at M drawn so far apart that the sparks only passed singly, then if a similar conductor, C' , be brought up to b , a stream of sparks was immediately observed. This action of C' could only be explained by supposing the current in gh was oscillatory.

The reason that a powerful induction-coil gives rise to oscillatory motion is, that, first, it charges the terminals C and C' to a high potential; second, it produces a-spark in the intervening circuit; and, third, as soon as the discharge begins, the resistance of the air-space is so much reduced as to allow of oscillatory motion being set up. If the terminal conductors are of very large capacity (for example, if the terminals are in connection with a battery), the current of discharge may indefinitely reduce the resistance of the air-space; but, when the terminal conductors are of small capacity, this must be done by a separate discharge, and therefore, under the conditions of Hertz's experiments, an induction-coil was absolutely essential for the production of oscillations.

Hertz slightly modified the form of apparatus used to that shown in Fig. 4, where the conductors C and C' were in the same straight line, three metres apart, with the discharger B at the centre. With this arrangement, sparks were obtained in the micrometer circuit when its distance from BC' was one and a half metres. Hertz replaced the micrometer circuit shown in Fig. 4 by another, which

FIG. 4.

consisted of two wires parallel with BC' , with knobs at their ends, there being a micrometer, M , at the middle. Sparks were obtained at the micrometer, as with the other form of circuit. When the knobs at B were drawn so far apart that there was no spark between them, there was still a spark at M due to the electrostatic effect of charging C and C' . By bridging across M with a damp thread, this effect was got rid of; but, when there were sparks at B , there were sparks at M , even with the thread. So the thread was sufficient to afford a passage to the comparatively slow alternations of the coil-discharge, but was not sufficient to provide a passage for the immeasurably more rapid alternations of the oscillatory current.

If there really are oscillations of the nature of a regular vibration, then an oscillatory current of a definite period would exert a much greater inductive effect upon one of equal period than upon one differing from it; that is, we ought to get resonance phenomena from currents, as from sound-vibrations. If two circuits are taken having as nearly as possible equal periods of vibration, the effect of one on the other will be diminished by altering either the capacity or coefficient of self-induction of one of them, as a change in either of these would alter the period of vibration of the circuit.

(To be continued.)

ANOTHER ELECTRIC ROAD AT ATLANTIC CITY, N.J.—We take great pleasure in announcing in this issue of our paper a most important indorsement of the electric system of street-railway propulsion. This indorsement comes from the Pennsylvania Railway Company, who have during this last week, through the general managers of that company, closed a most important contract with the Sprague Electric Railway and Motor Company for the complete equipment of their system of electric street-railways at Atlantic

City, N.J. Before awarding this contract for the equipment of this road, the Pennsylvania Railroad appointed a committee who should have charge of making a most minute and careful investigation of the merits of all the different systems of street-railway propulsion, both electric and cable, now in use. The committee in charge of the investigation were composed of mechanical and electrical experts of the highest class, and of wide reputation. The period of investigation extended over five months, and during this time the committee visited all the principal electric railways and cable roads which are in operation in this country, and carefully examined the operation of each. The Sprague Company are certainly to be congratulated upon securing this contract.

WEST END ELECTRIC ROAD AT BOSTON.—The West End Electric Railway at Boston is running very successfully, and carrying a large number of passengers each day between Park Square (one terminus of the road) and Brighton (the other terminus of the road). The cars run fast, and are under quick and perfect control. The residents in Brookline who use the cars regularly in coming into Boston and returning are enthusiastic over the time saved over the ordinary horse-car. The change of the overhead to the underground system is made very quickly, and without stop, so that no delay is experienced at this point. The car-drivers, or "motoneers," as some Bostonians persist in calling them, are not expert electricians, but simply street-car drivers, who have been detailed to operate the electric cars, and who have learned their necessary duties very quickly. All of these old drivers are enthusiastic over the ease with which an electric car can be driven, and are well pleased with their new position. On the 20th of January a very heavy snow-storm reached the city, and covered the tracks of the railway to the depth of from two inches to a foot. The electric snow-ploughs, which are being equipped by the Sprague Company for use by the West End Road, had not been finished, and the cars were obliged to run without this aid for clearing the tracks. In spite of this, the cars ran very successfully over the entire distance of the roads, clearing their own way, and carrying large numbers of passengers. The president of the road and the directors expressed themselves as well pleased with the demonstrated efficiency and strength of the electric road, as exhibited during the snow-storm, even without the aid of the regular Sprague electric snow-ploughs. The *Boston Herald*, in an editorial of Jan. 17, in commenting on the road, said, "Those who have made the experiment of taking a ride on the new electric railway on Beacon Street must have come to the conclusion that this method of securing rapid transit in the suburban wards is one of the most promising that has yet been brought forward in this city. The speed attained, where the conditions are favorable, is quite equal to that of the elevated railroads in New York City, while the structures supporting the electric wires are by no means as much of a disfigurement as it was at one time supposed that they might be." So long as a mixed service is maintained,—that is, so long as some of the cars are drawn by horses,—the full advantage of the electric system cannot be realized. The speed of the electric car has to conform to the speed of the horse-car which may be in front of it; but, if the experiment proves as successful as there is now every reason to think that it may, the West End Company will before long feel compelled to substitute electric for animal power in the service of all of its lines. When that change is brought about, the speed that can be made, even in the centre of the city, will be very much accelerated over the average speed of to-day.

A SOUTHERN ELECTRIC RAILWAY STARTED.—During the past week the Asheville Electric Street Railway, which has been in course of construction for the last month under the Sprague Electric Railway and Motor Company of New York, was successfully put in operation. The first trial trip of the motor-cars was made on Jan. 21, in presence of the president, Mr. W. P. Penniman, jun.; superintendent, Mr. J. H. Barnard; and a number of prominent citizens,—Capt. T. W. Patton, Gen. Jonstone Jones, Dr. S. D. Pelham, and about sixty others; some being stockholders in the road, and others interested, directly or indirectly, in the success of the enterprise. The test proved a great success. The run was made over the entire distance of the line, about two miles, in less than eight minutes, carrying a large number of passengers. The citizens of Asheville are enthusiastic over the new electric line, and the direc-

tors of the road express themselves as very well pleased with the successful performance of the motor-cars.

A NEW SYSTEM OF ELECTRICAL DISTRIBUTION.—One of the problems which has claimed the attention of inventors in the past few years has been the conversion of high-tension to low-tension electric currents. The object is to distribute electric energy at a high potential, using comparatively small wires, and at the points of consumption to reduce the potential to that demanded by safety and the requirements of incandescent lighting. A large part of the cost of an incandescent electric plant is in the wires used for distribution; and the size of the wire required to distribute a given amount of energy varies inversely as the potential used. One of the most successful converter systems is that

THE DICKERSON SYSTEM OF ELECTRICAL DISTRIBUTION.

used by the Westinghouse Company, where alternating currents are employed, and the reduction is effected by transformers,—induction-coils working backward. But there are some disadvantages in the use of alternating currents, and many attempts have been made to invent a continuous-current converter, that will do for continuous what the transformer does for alternating currents. Storage-batteries would offer an ideal method of effecting this, but for their cost and depreciation. Several mechanical methods have been tried, among others a motor-generator arrangement,—a combined motor and dynamo, the former supplied from the high-potential circuit, the latter supplying current at a low potential to the local circuit. Other plans have been proposed in which the main circuit is interrupted and advantage is taken of its inductive effect on the secondary circuit. None of these systems, however, are in successful operation on a large scale. Mr. Edward N. Dickerson, jun., of this city, received last week (Jan. 22) a patent on an improvement in his method of converting high-tension into low-tension currents. Feb. 14, 1888, a patent was granted Mr. Dickerson for a method of converting a direct high-tension cur-

rent into an alternating low-tension current; and by his recent improvement he is able to obtain a continuous low-tension current, which is a considerable advantage if the resulting current is to be used for a motor or for electric plating. The accompanying figures will make it clear how this result is obtained. A high-tension current flows out upon the circuit *a*, and returns to the generator by the circuit *b*. By the switch *L* it passes through the motor *C*. On the shaft of this motor is arranged the double reversing-commutator *BB*, the sections of which are alternately connected with the circuit *d* and with the circuit *g*. The current upon the circuits *g* is a high-tension reversing current, and operates the converter *F*, which converts the reversing high-tension current into a reversing low-tension current. This induced alternating current passes to the reversing-commutator *JK*, by which the reversing currents are rectified. It is of course essential that the two commutators shall move synchronously, and the commutator *JK* should be so adjusted on the shaft as to allow for the time required by the converter. The switch *EF* may be omitted; but by it it is possible to throw any house into circuit from the central office.

THE WESTINGHOUSE AND UNITED STATES COMPANIES.—An agreement is reported between these companies whereby their interests are united. The United States Company is one of the oldest electrical manufacturing companies, and has a large factory in Newark, N.J. The Westinghouse Company was already the lessee of the Consolidated and Sawyer-Man Electric Companies of New York, and the owner of the Waterhouse Electric Company of Hartford, Conn., and the Tesla Electric Light and Manufacturing Company of Rahway, N.J. The new combination has a manufacturing capacity of over 15,000 lamps a day, and the two companies own and control about 700 patents in every branch of electrical invention.

NOTES AND NEWS.

It is announced that a post-graduate department in electrical engineering will soon be established by the trustees of Columbia College, this city. A beginning will be made upon an economical scale, and the facilities will be increased in proportion to the patronage, which it is believed will increase rapidly, as New York is a city in or near which all or nearly all of the many applications of electrical science may be studied in practical operation. The course will be open to graduates of all scientific schools.

— An electrical exhibition will be held in the Chicago Exposition Building, in connection with the National Electric Light Association Convention on Feb. 19, 20, and 21. Many exhibitors have already secured space, the electric railway companies being especially forehanded in that respect. The exhibition, though not intended to be of long duration, promises to be interesting and important.

— The *Journal of the Society of Arts* reports the discovery of a new textile on the shores of the Caspian. This plant, called "kanaff" by the natives, grows in the summer, and attains a height of ten feet, with a diameter varying from two to three centimetres. By careful cultivation and technical manipulation, M. O. Blakenbourg, a chemist and engineer, who has made a special study of kanaff, has obtained an admirable textile matter. It is soft, elastic, and silky, gives a thread which is very tough, and can be chemically bleached without losing its value. The stuffs manufactured out of kanaff, and then bleached, can be successfully dyed in every shade of color, and would compete with any of the ordinary furnishing materials now in use. But it is particularly for making sacks, tarpaulin, ropes, etc., that this new textile, from its cheapness and its extraordinary resisting power, might defy all competition. Its specific weight is much less, but its resistance much greater, than those of hemp. Thus, a cord of 8.25 millimetres diameter, woven with the hand out of three threads of kanaff, requires a weight of 180 kilograms to break it. A cord half an inch thick, manufactured at Moscow, did not break till the weight of 625 kilograms was reached. When it is considered that Russia annually consumes more than one hundred and fifty millions of sacks, a third of which are imported, it may be easily seen that the appearance of this new textile on the Russian market is an event of no slight importance.

IT APPEARS that *Science* will have to widen the field of its activity in combating politics in the schools. New Jersey is suffering, apparently, as New York City is, but with this important difference: in New York the politicians are entrenched; in New Jersey they are seeking to gain possession. The situation is this. A year ago an inefficient State superintendent of public instruction was superseded, on the expiration of his term of office, by Col. Charles W. Fuller, a lawyer of high standing, and a man of force and character. In one year he has revolutionized the administration of the office. On every side evidences of new life and activity are to be seen. The best and most useful teachers' institutes in the history of the State were held last autumn, with excellent results. Manual training, compulsory education, increased salaries, and other important measures, have been aided by Col. Fuller's administration. It so happens, however, that Col. Fuller is a member of a certain political party, which is not the one in control of the legislature this winter. In this the politicians have found their opportunity, and, by arousing partisan passions, are straining every nerve to legislate Col. Fuller out of office. It is not believed that this disputable scheme will succeed, for every manly and fair-minded legislator, of whatever party, will oppose carrying politics into the schools. If the press of New Jersey expose the character of the contemplated legislation, it will surely fail.

ON THE 26th instant the board of naval officers continued its experiments with Capt. Zalinski's gun, the firing of which was to determine the accuracy of the range of the projectiles, which must, according to the requirements, fall within a rectangle 50 by 150 feet. The ranges were at 200 yards, 1,000 yards, and one mile; and although nothing positive can be stated, as the official report has not yet been made public by the Navy Department, it is confidently believed that the trial, which showed effective action of over 50 per cent of the shots fired, will be a triumph for the company that has so boldly attempted to solve the problem of projecting large masses of high explosive at a sufficient rate of speed to insure accuracy in the flight of the shell containing the explosive. Should the trial be considered as not satisfactorily answering every requirement of the specifications, it would be some two weeks before another trial could take place, owing to there not being a sufficient number of projectiles on hand. The official table of data of the trial, including the range of each projectile, is given below. It will be seen from the column of ranges that five projectiles fell within a rectangle of 50 feet by 100 feet, or the limits specified by the contract. These shots were Nos. 1, 4, 5, 6, and 9 in the order of firing. There being nine shots fired in all, it is seen that 50 per cent came within the rectangular limits. But the question is, Will the board consider the spirit of the contract fulfilled by the above, or, if the members do report favorably on the gun's accuracy, will the secretary of the navy demand a second trial and a rigid adherence to the contract provisions, as shown in the report of the trial? The following is the official table of Saturday's trial:—

No. of Fire.	Ranges.	Weight of Projectile.	Loss of Pressure.	Time of Flight.
1	2,177	450	125	Lost.
2	2,017	452	122	11 3/4
3	2,009	453 1/2	105	12 1/4
4	2,159	451 3/4	123	12
5	2,156	445	125	11 3/4
6	2,127	448 1/2	123	12*
7	2,055	454	110	11 2-5
8	2,090	483	220	13
9	2,154	440	125	12 4-5

* Approximate.

The elasticity of the requirements under which the trial was conducted may permit of the above being taken as satisfactory to the government, inasmuch as the firing at the 1,000 and 200 yards' ranges in itself proved the accuracy of the new guns.

ALL SCIENTIFIC MEN in government employ whose works will pass through the Government Printing-Office will be gratified, that, by the common consent of those who know him best, Alexander R. Hart of this city has been put forward as the best qualified and most available candidate for public printer under the new administration. For several years he has prepared engravings and illustrations of a scientific nature for the Smithsonian Institution, the United States Fish Commission, and other departments of the government. He has long been at the head of one of the best-organized and most thoroughly equipped printing and engraving establishments in this city, if not in the world. He is acknowledged to be a man of splendid executive ability, and he possesses a thorough knowledge of the printing and engraving business, down to the most minute details. He has worked his way from the foot of the industrial ladder by just such qualities as fit him for the position now suggested for him, where he would command the respect not only of those under his supervision, but also of all others who, socially or officially, should be thrown into contact with him.

SOMETHING ABOUT TORNADES.¹

WHERE atmospheric equilibrium is violently decomposed and the agitation covers but a very limited area, the centripetal force becomes much greater than in the case of cyclones. The gyrations are exceedingly rapid and very near the centre; in fact, the violence is greatest at the centre, and diminishes rapidly to the external parts of the disturbance, where the gyrations cease altogether. This form of disturbance is called a tornado. In order that conditions may become favorable for tornadic development, the atmosphere must assume the unstable state. This state will be engendered whenever the rate of decrease of temperature is greater in the surrounding quiet air than it is in the mass of ascending air. The adverse or counter movement of northerly and southerly winds induces the unstable state, because it makes the rate of decrease of temperature greater in the quiet air than in the column of ascending air; that is, the upper strata of the air will be made colder, and the lower strata warmer.

What are known as local storms, under this class of motions of the atmosphere, are not affected by the rotation of the earth upon its axis, because the area of disturbance is too small. The progressive motion of tornadoes to the north-east arises from the fact, that, as they always form in the south-east quadrant of an area of low barometer, they must come within and under the influence of the general drift of the atmosphere on that side of the "low," which, according to the law of atmospheric circulation about the centre of an area of low pressure, is always to the north-east.

The condition of tornado-formation in regard to heat is simply that of unstable equilibrium for saturated air at the existing temperature, the other condition being that the air shall have a gyratory motion relative to some central point, arising from any cause whatever. In the unstable state, the lower strata of the atmosphere are liable to burst up through the upper layers at any point where there may chance to exist some slight predetermining cause, which is never wanting, arising from local conditions of temperature and moisture.

When an upper motion of the atmosphere is started at any point, the air thus engaged is kept warmer, and therefore rarer, than the region immediately surrounding it. This continues as long as the ascending current is supplied with air nearly or quite saturated, or until, from an inversion of the air in the lower strata, the state of unstable equilibrium is changed. The violent whirling motion of the air which characterizes the tornado is dependent upon a pre-existing disturbed and gyrating state of the atmosphere. The case is somewhat similar to that of water in a shallow basin running out through a hole in the centre. If the initial state of the water is that of perfect rest, it flows directly toward the centre with a very slow velocity; but, if there is the least initial disturbance of a gyratory character when the water first begins to flow, it soon runs into rapid gyrations around that centre.

As we have shown, therefore, there are two principal conditions upon which the occurrence of tornadoes depends, and in the absence of either of which they cannot take place. The one is the state of unstable equilibrium of the air, and the other a circulation motion with reference to any centre of disturbance. It is not imperative that the central area shall be stationary, but simply that the motion of the air around it shall be such that when the latter is drawn in toward the centre it will take a gyration around it. When these two principal conditions are present, there is scarcely ever wanting the secondary condition, which, through the effect of some slight initial disturbance, gives rise to an upward burst of the air through the overlying strata. The places and time most favorable to the development of unstable equilibrium and a gyratory motion of the atmosphere are those in which tornadoes are most likely to occur. Of these two conditions, the unstable equilibrium is the most important, since it more rarely occurs than the other, which is scarcely ever so entirely absent as not to give some slight gyratory motion, which becomes violent very near the centre. The question naturally occurs, Where are the places on the earth's surface, and what is the time, when conditions are most favorable for the development of tornadoes?

First, as to places. These are found where, in the general motions of the atmosphere as affected by continents and mountain-ranges, currents of the air at the earth's surface, which come from a warmer latitude, or at sea from a much warmer continent, are caused to flow under the colder upper strata, where the normal motion is nearly eastward, and where consequently the temperature is the normal one, not affected by such motions as take place in the lower strata: in other words, tornadoes are most likely to occur in regions where warm, moist air flows underneath a colder and dryer upper strata, coming from another direction. Such regions are found particularly in the Mississippi, Missouri, and Ohio valleys, and in Alabama, Georgia, and the Carolinas. The other condition — viz., a relative gyratory motion with regard to any point — is found to an unusual extent in the regions above named, especially in the winter season, which fact accounts for the frequent occurrence of tornadoes in the Southern States during the winter and spring, and occasionally in the Mississippi and the Ohio valleys.

Second, as to time. The summer season is the most favorable for tornadoes, when the interior of the continent is warmed up, and the air of the lower strata is drawn from lower latitudes far up into the northern portions of the country on the eastern side of the Rocky Mountains, and the isothermal curve is deflected very decidedly toward the north. From this cause the temperature of the lower strata of this region becomes much higher than that of the superdominant strata; and, if this condition does not of itself induce the unstable state, it is readily accomplished by the addition of any small effect from some other cause, as from extremely warm weather, in which the earth's surface and the lower air strata become abnormally heated.

The great moisture of the air in the southerly winds is also favorable to the induction of the unstable state, since such a change is more readily brought about in air nearly or quite saturated. The southerly currents curving eastward from the Rocky Mountain and Appalachian ranges give rise to a general air movement of considerable force toward the Atlantic Ocean, as the result of which, cold counter currents pass southward to Texas, east of the Rocky Mountains, and to Florida over the Appalachian range, somewhat after the manner of the Arctic currents which flow southward to Florida, between the Gulf Stream and the coast of the United States.

In the summer season this flow of cold air southward is confined to a comparatively narrow belt east of the Rocky Mountains, for at that time the warm, moist currents of the Gulf are drawn very far to the north and west. At this season the northern part of Texas has the same mean temperature as Minnesota, the isotherms being nearly north and south in direction; and the temperature gradient between the warm southerly winds on one side, and the cold northerly currents on the other, is similar to that of the cold wall between the Gulf and Arctic currents.

In the winter and spring the flow of cold air southward from the higher latitudes extends to the Appalachian range, where it overflows the warm, moist southerly currents from the East Gulf and South Atlantic coast. It is this tendency of the air to flow in contrary directions, where the conditions are most favorable to produce the unstable state of the atmosphere, that pronounces the regions here indicated as the "battle-ground of tornadoes." The word "low," as is quite well known, marks upon the weather-map the centre of lowest pressure as indicated by the barometer and direction of the wind. This is practically the centre of the general storm or atmospheric disturbance.

1. The conditions for the development of tornadoes are most favorable in the south-east quadrant of a "low:" in fact, they are not to be looked for in any other portion of the general disturbance. 2. Tornadoes very generally accompany a "low," for the reason that the condition of unstable equilibrium necessary in the formation of a tornado is also required in the "low," at least in the upper cloud-region. 3. The unstable state in a "low" very rarely extends down to the earth's surface, so that tornadoes are not necessarily visible in every general storm. 4. There are frequently secondary whirls, incipient tornadoes, in the cloud-region of a "low," the effects of which do not reach down to the earth's surface, and the only visible effect above is the formation of a local

¹ Portion of a paper read before the National Geographic Society of Washington, Nov. 16, 1888, by J. P. Finley.

cloud a little denser and darker than the clouds are generally. 5. A hail-storm is an incipient tornado in the cloud-region of a "low." 6. Tornadoes always occur in the south-east quadrant of a "low," and at distances generally of from 200 to 500 miles from the centre. They are not likely, however, to occur in the south-west and north-west quadrants of a "low," because the currents and counter currents there are nearly east and west; and hence the effect is neutralized, tending neither to produce nor destroy the unstable state. As the "low" progresses eastward, the region of country lying, on the average, about 350 miles to the south and east of the centre of the general storm at any time, is the region within which tornadoes may be expected.

The destructive violence of a tornado is sometimes confined to a path a few yards in width, or it may widen to the extreme limit of eighty rods. The tornado, with hardly an exception, occurs in the afternoon, just after the hottest part of the day. The hours of greatest frequency are 3.30 to 4 P.M., and 4.30 to 5 P.M. The destructive power of the wind increases rapidly from the circumference of the storm to its centre. Observations with a single barometer will not indicate the approach of a tornado, however near the position of the instrument to the path of the storm; and such observations are of value in this connection, only when a number of them are displayed upon the weather-map. The tornado season includes the months of March, April, May, June, July, August, and September. There are, however, cases in a long series of years where tornadoes have been reported every month of the year. The months of greatest frequency, as determined from a record of 206 years, are April, May, June, and July. The month of greatest frequency is May, April coming next on the list. The State in which the greatest number of tornadoes have occurred is Missouri, followed next in order by Kansas and Georgia. The 425 tornadoes and "windfalls" recorded in Wisconsin far exceed the number from any other State; but little weight can be given this fact, owing to the want of a similar investigation of the subject of "windfalls" in other States. The violence of tornadoes expressed relatively by States places Missouri first, succeeded by Iowa and Alabama. By "violence" in this sense is meant the most completely developed storms with perfect conditions longest sustained.

Considering the entire record of eighty-eight years (years of record from 1682 to 1888), nearly 4,000 persons have been reported killed, and 6,000 injured. This record is very imperfect, owing to the large number of cases in which the killed and wounded were not definitely reported. The States in which tornadoes have proved the most destructive to life are in relative order as follows: Missouri, Mississippi, Iowa, Illinois, Minnesota, Wisconsin, and Ohio.

Considering the reported valuation of property destroyed, the following States have experienced the most destructive storms, and in the order named: Missouri, \$94,325,000 in forty-seven years; Ohio, \$87,737,500 in eighty-four years; New York, \$67,000,000 in one hundred years; Kansas, \$64,000,000 in twenty-nine years; Georgia, \$56,500,000, in ninety-three years; Minnesota, \$50,750,000 in thirty-three years; Iowa, \$49,575,000 in forty-five years; South Carolina, \$46,875,000 in one hundred and twenty-seven years. These values are necessarily approximate, owing to the imperfect reports, and it is believed that they fall considerably short of the actual amount of loss.

It is a difficult matter to obtain reliable estimates of the actual value of property destroyed by tornadoes in the United States, since the date of the earliest records; viz., June, 1682. Although the average yearly occurrence of these storms has probably remained unchanged, and will continue so, yet the value of the property subject to destruction by them has increased enormously, and the amount is constantly enlarging as the country advances in wealth and population. Where fifty years ago the tornado swept a barren plain or trackless forest, it now crushes and overwhelms prosperous cities, and devastates rich and populous agricultural districts.

The approximate aggregate loss to property by tornadoes, considering the number of storms reported, is nearly one billion of dollars. Considering the number of years embraced in the period of observations and the average yearly number of tornadoes, the amount is nearly ten billions of dollars. This estimate is probably

in excess of the actual loss, because no allowance is made for the many storms which have occurred since 1682 without appreciable waste. Taking the past thirty years as affording more satisfactory information, and considering the average yearly occurrence of tornadoes as 146, the approximate aggregate property loss foots up about two billions of dollars.

A comparison of yearly values, as obtained from carefully prepared tables showing the number and geographical distribution of tornadoes, might lead one to the conclusion that these storms were on the increase. Such a deduction would certainly be erroneous, and for the following reasons. First, From a careful investigation of the origin of tornadoes and their geographical distribution, there is every reason to believe that these storms were as frequent and violent two hundred years ago as now. Moreover, there appears to be no cause for any unusual change in the annual frequency of tornadoes for a like period to come. Second, It must be considered that during the past ten years the Signal Service has had great facilities for collecting reports; and the rapid growth of the country, with a greater zeal of the press, has brought to light the occurrence of many storms which otherwise would not have been reported. Third, The statistical tables are not sufficiently complete, especially prior to 1875 (without which period it would not be safe to make deductions), to permit of reliable conclusions as to periods of maximum and minimum occurrence. It is not unlikely that such variations exist, and that they depend upon the relation of heat and moisture to the general condition of the atmosphere. The more frequently the unstable state of the atmosphere is produced, together with a relative gyratory motion, the more favorable are the conditions for the occurrence of tornadoes, and *vice versa*. Fourth, In the region between the 95th and 107th meridians, tornadoes still occur without causing much damage, because of their passage over thinly settled portions of the country. Owing to this fact, little attention is given to these storms; but this indifference will soon disappear, as the country rapidly settles up and every appearance of the cloud-monster is marked by death and destruction. Fifth, The years (118) that are missing in the period of 206 years from 1682 to 1887 inclusive are not to be considered as years in which no tornadoes occurred, but as years in which records are wanting owing to failure of observations.

Considering the past ten years (1878 to 1887 inclusive) as furnishing reliable and exhaustive records of tornadoes, and that the period prior to 1878 (196 years, 1682 to 1877 inclusive) is deficient owing to want of facilities in collecting reports, we may give an interpolated value for each of these latter years, as determined from the complete ten-year record. This value is found to be 146, which means, that, on the average, 146 tornadoes will occur in the United States.

Applying this constant to existing records, we have a grand total of storms from 1682 to 1887 inclusive (206 years) of 30,076 tornadoes, instead of 2,435 actually observed and reported. This would indicate a failure to report the occurrence of about 27,641 tornadoes which have probably passed over portions of this country since 1682. In that year a very destructive tornado, with distinct funnel-shaped cloud, visited New Haven, Conn., at 2.30 P.M. on the 10th of June. It is the very long interval of 118 years, during which records are entirely missing, that makes the discrepancy so great in the grand totals.

No well-authenticated case of a tornado has been reported from the region of country lying west of the 105th meridian, and it may be generally stated that these storms do not occur in the United States west of the 100th meridian. The cause for this is found in the lack of favorable conditions, on account of the dryness and the lower temperature of the air, and the want of uniformity in the direction and force of surface currents. Violent straight winds, attended with considerable destruction to property, have been reported several times in the past fifteen years, from southern and central California, Arizona, New Mexico, and Montana.

Much has been said and published concerning the influence of forests upon the occurrence and destructiveness of tornadoes, and many people believe that where timber grows in great abundance, tornadoes cannot occur. By comparing the number of tornadoes in each State with the acreage of forests, as estimated in the last census report, it is found that the latter appear to have no percep-

tible influence in preventing the occurrence of tornadoes, or in assuaging their violence.

In this connection, it should not be forgotten that the conditions which give rise to the development of tornadoes exist in the cloud-regions of the atmosphere, and not at the surface of the earth. Forests would prevent the occurrence of whirlwinds, because these phenomena depend upon the unstable state of the atmosphere at the earth's surface, where the conditions are favorable for the sun's heat to accumulate in the surface strata of the soil, and thus superheat the air resting upon it. A heavy growth of timber or rank vegetation will prevent this action of the sun's rays.

Whenever a tornado-cloud encounters a forest, the destruction is complete and terrible. The forces of the tornado-cloud are quickly brought into operation, and maintained continuously while the phenomenon exists. They are not affected by having to meet in rapid succession totally different objects, different in size, strength, shape, materials, composition, structure, relative position, etc.

The width of the path of destruction, as determined from the records of 88 years, varies from 10 to 10,560 feet, the average being 1,369 feet. The length of the tornado-track varies from 300 yards to about 200 miles, the average being 24.79 miles. The velocity of progression of the tornado-cloud varies from 7 to 100 miles per hour, the average being 44.11 miles. These extremes may often occur in different portions of the track of a single tornado. The shortest time occupied by the tornado-cloud in passing a given point varies from "an instant" to about 20 minutes, the average being about 74 seconds.

The month of greatest frequency, that is, the month embracing the largest number of days in which tornadoes occurred, is May. The prevailing direction of the progressive movement of the tornado-cloud is north-east. The vortex wind velocities of the tornado-cloud vary from 100 to 500 miles per hour, as deduced from actual measurements. Velocities of from 800 to 1,000 miles per hour are extremes that have been reported, but may not be altogether reliable. Theoretical velocities of 2,000 miles and over per hour, based upon certain assumed atmospheric conditions, have been deduced. Such velocities are mathematically possible, but not meteorologically probable.

The concomitants of the tornado are, an oppressive condition of the air; the gradual setting-in and prolonged opposition of northerly currents and southerly currents over a considerable area; a high temperature, and the presence of considerable moisture; a gradual but continual fall of the thermometer with the prevalence of northerly currents, and a rise with the predominance of southerly; a rapid decrease of temperature with increase of altitude; a decided gradient of temperature across the line of progressive movement; huge masses of dark and portentous clouds in the north-west and south-west, possessing a remarkable intensity of color, usually a deep green; a remarkable rolling and tumbling of the clouds, scuds darting from all points of the compass towards a common centre; hail and rain accompanying the tornado, the former either in unusual size, form, or quantity, and the latter either remarkable in quantity or size of drops; the presence of ozone in the wake of the tornado; a remarkable roaring noise, like the passage of many railroad-trains through a tunnel.

The cloud generated by the vortex assumes the form of a funnel, with the smallest end towards the earth. This explains the remarkable contraction of the storm's path. Upon reaching the earth's surface, the vortex has four motions: viz., first, the whirling or gyratory motion, always from right to left; second, the progressive motion, generally from some point in the south-west quadrant to some point in the north-east quadrant; third, the curvilinear motion; fourth, oscillatory motion.

The characteristic effects of a tornado are, objects are drawn towards the vortex from every point of the compass; objects passing into the vortex are thrown upwards and outwards by the vortical action of the engaged air; structures are literally torn to pieces by the vortical action of the air, evidence of which is afforded by the fineness of the *débris*, and also its disposition in the storm's path; the *débris* is thrown inward from each side of the storm's path; light objects are carried to great heights and also to great distances; objects are carried inward and upward by the centripetal, and outward by the centrifugal, forces of the vortex; weight

and size are conditions which generally present immaterial values to the power of the tornado; persons are stripped of clothing; fowls and birds are denuded of feathers and killed; trees are whipped to bare poles; heavy objects are carried for miles in the air; long and heavy timbers are driven to considerable depths in the solid earth; the vortex is completely filled with flying *débris*; timbers are driven through the sides of buildings; sand and gravel are driven into wood; the strongest trees are uprooted, or twisted off near the roots; men and animals are terribly mangled by contact with flying *débris* and by being rolled over the ground for a considerable distance; in the path of the storm all vegetation is destroyed; railroad-trains are thrown from the track; iron bridges are completely dismantled and carried from their foundations; heavy bowlders, weighing tons, are rolled along the earth; the largest railroad-engines are lifted from the tracks on which they rest; all objects, whether metal or non-metallic, magnetic or non-magnetic, simple or compound, animate or inanimate, are acted upon in a similar manner.

THE SITUATION IN SAMOA.

THE continuous disturbances on the Samoa Islands, and their bearing upon questions of great political importance, give to these islands a special interest. The group consists of thirteen islands, only three of which are of commercial interest,—Savaïi, Upolu, and Tutuila. Savaïi is the largest island of the three, measuring some 40 miles from east to west by 20 miles from north to south, and having an area of 700 square miles. It has no harbor of any importance, and in this respect it contrasts strongly with Upolu and Tutuila. The little bay of Mataatu, in the extreme north of the island, is the only place where large vessels can anchor; but even it is not safe from November to February. The interior of the island is occupied by two mountain-ranges of volcanic origin. It has no rivers or streams, the water filtering away through the porous soil. Where the mountains approach the coast, the latter is very steep and inaccessible, while in other places a well-wooded strip of alluvial land is found, on which numerous villages are situated. The sterility of the interior of this island has always been a barrier to all settlement or cultivation, and even to the visits of travellers and explorers.

Upolu, which covers an area of 550 square miles, is also mountainous, but it is well wooded and fertile, and possesses several considerable streams, although they are, of course, not navigable. On the northern coast of this island lies Apia, the chief town of the whole Samoan group. It is prettily situated, having a background of mountains thickly wooded, and a foreground of harbor and coral reefs. The harbor consists of two portions, the most westerly being the best for vessels that intend to remain for any length of time, especially during the rainy season. For sailing-craft, a steady breeze is absolutely necessary on entering or leaving the harbor, as a strong current sets along its entrance.

Passing down the coast east of Apia, a succession of beautiful bays are met with. At the distance of from half a mile to two miles from the shore a coral reef protects this portion of the island for nearly twenty miles. At high tide canoes and boats can pass between this and the mainland, and thus a great deal of the insular traffic is carried on.

As seen from the sea, there are not many islands in the Pacific that present a more beautiful or picturesque appearance than Upolu. It shows a bold and majestic front, the central range being not less than 3,000 feet high, and wooded almost to its summit. It is throughout a very fertile island, and fully equal to the best portions of the Fiji group.

Tutuila is about 17 miles long and 5 broad. On its southern side is the deep bay of Pagopago, which almost cuts the island in two. This harbor, which is one of the best in the whole South Pacific, is surrounded by hills from 2,000 to 3,000 feet high. Surrounding the harbor at their base is a small strip of level land. The harbor is half a mile wide at its entrance, and runs north and south for a distance of a mile, when it turns in a westerly direction, and opens out into a fine sheet of water. It is somewhat difficult for sailing-vessels to leave, in consequence of the trade-winds blowing directly into it; but for steamboats it is unsurpassed by

any harbor among all islands of the South Pacific. Here vessels of any size can lie at anchor, secure from every wind, all the year round. It is well adapted as a coaling station or for refitting and repairing ships, and affords, moreover, plentiful supplies of timber, food, and water.

Upolu, and to some extent Tutuila, have attracted a considerable number of American and European capitalists, the latter mostly Germans; and a large portion of the land has passed into the hands of foreign residents, who number about three hundred. The bulk of the foreign trade belongs to the successors of the famous Hamburg firm of J. C. Godefroy & Son. Cotton, coconuts, and bread-fruit are cultivated for export; and maize, sugar, coffee, etc., for local consumption. Copra (dried coconuts) is the most important article of trade. In 1881 the planters had about 1,800 laborers from the Line Islands, New Britain, New Hebrides, etc., the Samoans being too independent to hire themselves out.

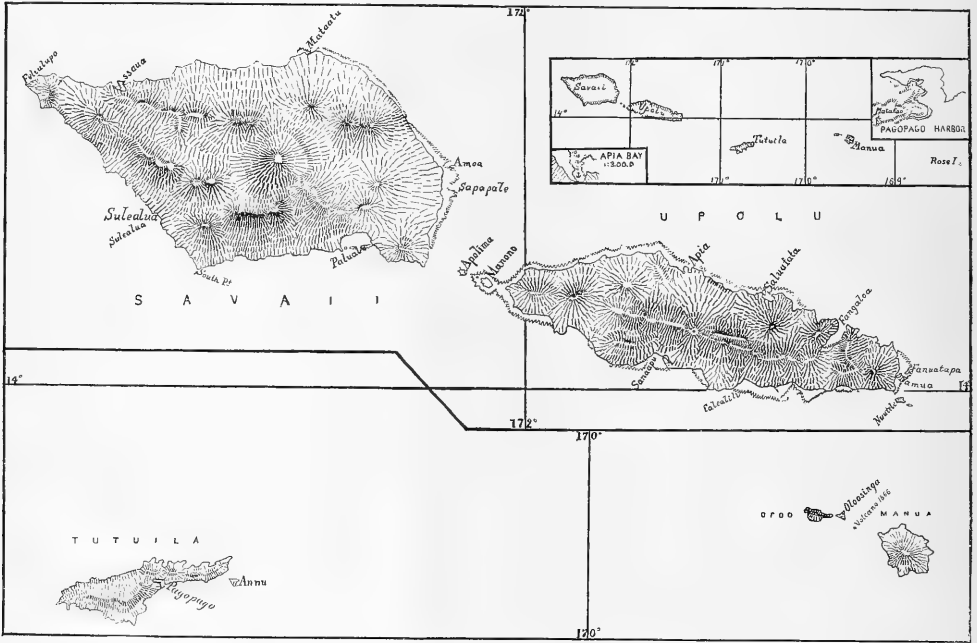

under the protection of German guns. Tamasese is, of course, as much of a puppet in the hands of the Europeans as Malietoa has always been. The conflict between the native parties has reference not so much to whether the one or the other person be king, as to the question of whether Germany or England-America shall retain the upper hand.

HEALTH MATTERS.

Poisonous Milk.

PROFESSOR L. P. KINNICUTT of the Worcester (Mass.) Polytechnic Institute reports to the *Boston Medical and Surgical Journal* five cases of poisoning by milk in which, upon chemical analysis, he found tyrototoxic.

The milk was in a pint beer-bottle with patent rubber stopper, and appeared and tasted perfectly fresh and good. After carrying it to the laboratory, it was allowed to remain in the tightly stop-

MAP OF THE SAMOA ISLANDS.

Among the natives of these islands dissensions have always been raging, and the European traders did not fail to take advantage of their internal wars. In 1860 the firm of Godefroy, which at that time encountered no considerable competition in the Pacific, stood on the side of Malietoa, a chief belonging to one of the most distinguished families of Samoa. Although Malietoa was never in reality ruler over the whole group of islands, he assuredly had the expectation of the first place in the country, and the royal title was formerly willingly given him.

Throughout the next twenty years, which passed with continuous dissensions among the natives, the Europeans who had gradually settled in Samoa, Germans, Englishmen, and Americans, found abundant opportunity to meddle in the quarrels of the inhabitants, which they did accordingly in the fullest measure. They sought, by taking sides with or against Malietoa, to strengthen respect for their nations, and thereby increase their commerce. Since Malietoa was influenced principally by Americans, the German Commercial and Plantation Society, who had originally supported him, took the opposing side, and in 1887 helped Tamasese to dethrone his old adversary. Before the recent uprising, a German, Tamasese's prime minister, was in reality possessor of all power,

pered bottle for one week before it was examined. The milk had by that time decomposed, separating into two layers. It was filtered through thick Swedish filter-paper, the filtrate neutralized with a dilute solution of sodium hydrate, placed in a separating-funnel, and shaken thoroughly with ether. A thick emulsion formed, and it was only after four days, and by the use of various mechanical means, that a separation could be effected. The ether solution was allowed to evaporate at the ordinary temperature, and the residue carefully tested. Re-actions were obtained which agreed perfectly with those given by Vaughan (*Journal of Analytical Chemistry*, vol. i. pp. 25 and 281) for tyrototoxic. There is therefore no doubt that the poisonous action of the milk was caused by the same poison that Vaughan found in the various cases cited by him.

A visit to the dairy from which the milk was obtained was made, and it was found that the herd consisted of fifteen Jersey cows, all in the best condition, well fed and cared for. The dairy supplies about forty families with milk, and the milk of all the cows is mixed together before subdividing it into the various portions; and as only one family out of the forty supplied with the milk, as far as can be found out, suffered from any poisonous effect, it proves that

the poison was developed after the milk had been delivered. This was also found to be the fact on questioning the servants of the family poisoned. The milk had been received in a tin can, which it was their business to keep clean, and it had been immediately subdivided into two portions. One portion was placed in an earthen dish to raise cream, and the other was used during the same morning as fresh milk, without causing the slightest trouble. The symptoms of poisoning were caused by the first portion, after standing over night. The above facts seem to show that the tyrotoxin was developed during the twenty-four hours after the milk was received.

The only explanation of its development that can at present be given is, that the cans used for obtaining the milk had not been thoroughly scoured with boiling water, and that a little old milk remaining on the inside edges of the can had undergone a peculiar fermentation, and had caused the development of a sufficient amount of tyrotoxin, during the twenty-four hours it had remained in a cool place, to produce the poisonous action.

Professor Kinnicutt describes thus fully the above case, as up to this time almost nothing is known as to the cause of the formation of tyrotoxin in milk. He has, he thinks, pointed out one way in which it may be developed, namely, the use of cans which have not been kept perfectly clean; but it is only by the careful examination of a number of cases that it will be possible to decide whether the formation of the poison is due solely to such causes.

THE PASTEUR INSTITUTE.—The Paris correspondent of the *New York Medical Record* contributes to that journal an interesting letter describing the opening of the Pasteur Institute, which occurred Nov. 14, in the presence of a large assembly presided over by the President of the Republic. The proceedings were opened by M. Bertrand, permanent secretary of the Academy of Sciences, who made a eulogistic speech on M. Pasteur and his numerous scientific researches. Dr. Grancher, M. Pasteur's principal assistant, then read a report of the work done in antirabic inoculations since the middle of 1885, when the first two human beings were inoculated. He stated that the number of persons treated at Paris in the Rue d'Ulm and the Rue Vauquelin during the years 1886-87 to July 31, 1888, was 5,384. The rate of mortality had been 1.34 per cent for 1886, for 1887 it was 1.12, and for 1888 it was 0.77 per cent. This rate of mortality comprises the deaths of persons who were affected with rabies the day after inoculation; but, remarked Dr. Grancher, even these figures are very striking, as the estimated mortality previous to the discovery of this method of treatment was 15.90 per cent as given by the reporter of the Council of Hygiene of Paris. Dr. Grancher informed his hearers that twenty laboratories for antirabic inoculations have been established in different parts of the world,—seven in Russia, five in Italy, and one each in Roumania, Austria, Brazil, Cuba, and the Argentine Republic,—while two more will shortly be opened at Chicago and Malta. The staff of the new institute are disposed of as follows: Dr. Grancher, with the assistance of Drs. Chantemesse, Charrin, and Terrillon, will attend to the department of the treatment of rabies; M. Duclaux, one of M. Pasteur's most ancient pupils, and now professor of biological chemistry at the Faculty of Sciences, will direct the laboratory of general microbiology; M. Chamberland is charged with microbiology in its relations with hygiene; Dr. Roux will teach the microbial methods in their applications to medicine; Drs. Metchnikoff and Gamaleia of Russia will study the morphology of inferior organisms and comparative microbia. The new institute will thus, as expressed by M. Pasteur, serve as a dispensary for the treatment of rabies, and will at the same time constitute a centre of researches for infectious maladies, as well as a centre of instruction for the study of microbiology, and will be open to medical men of all nationalities.

IS THE RACE DEGENERATING?—An English newspaper has been making a collective investigation regarding the questions given below: "1. Does your experience suggest to you that the race of Englishmen is degenerating physically? 2. Do you think that the great advance in the healing art is responsible for keeping alive much weak life that will in time affect the whole race injuriously? 3. Do you think that the increased indulgence in physical sports has, on the whole, a good influence on health? 4. Has it ever

struck you that probably the great attention paid to health in these days may be producing an anxiety about bodily ailments which is a disease in itself?" Answers have been received from a long array of practitioners, among whom are the names of eminent London physicians. The general view taken, according to the *Medical Record*, is that Englishmen are not degenerating, but that, on the whole, the race is improving in vigor.

TO INVESTIGATE DISEASES OF SWINE.—The commissioner of agriculture has appointed a commission, consisting of Professor William H. Welch of Johns Hopkins University, Dr. E. O. Shakespeare of Philadelphia, and Professor T. J. Burrill of the University of Illinois, to investigate the subject of swine-diseases in the United States, and the methods of their treatment and prevention.

MENTAL SCIENCE.

A Statistical Study of Sleep and Dreams.

THE application of general scientific methods to the problems of mental action has everywhere brought results of interest and value, and especially pleasing has been the success attending the study of the statistics of mental phenomena. Observations in themselves trivial, apparently accidental even, when intelligently grouped together, bring to light truths only dimly suspected and poorly understood. The errors of individuals in part disappear in the average, and results obtained by one method are controllable by others. A very striking innovation, with the help of the statistical method, into an obscure region of mental action, is attempted in a recent study coming from the University of Dorpat, Russia.¹ A series of questions were drawn up, and five hundred copies distributed. Of these, over four hundred were returned filled out; and it is upon these answers, which the author declares unexpectedly clear and accurate, that the conclusions of this paper are based.

Each observer, after stating his name, age, sex, and occupation, set himself to answering the following questions regarding his sleep and dreams. The persons were divided into three classes: 1. Students (151 in number); 2. Other males (113); 3. Females (142).

I.—Dreams.

1. Do you dream every night, frequently, seldom, never? "Nearly every night" was grouped with "every night," making 99 such answers; "frequently," "very frequently," etc., were reported 133 times; "seldom," etc., 153 times; and "hardly ever," or "never," 15 times; 6 were undecided.
2. Are your dreams vivid? This was answered affirmatively 216 times; negatively, 175; undecided, 15.
3. Can you well remember your dreams upon awakening? "Yes," 194; "no," 203; "undecided," 9.

II.—Sleep.

1. When do you go to bed?
2. When do you rise?
3. Are you tired in the morning upon awakening? Do you become tired early in the evening? 38 were tired both morning and evening, 104 in the morning only, 95 in the evening only, 169 at neither time.
4. How long does it take you to fall asleep? This question is difficult to answer, and the general tendency will be to overestimate the time; and this was partly taken into account.
5. Do you sleep through the night without awakening? "Yes," 261; "no," 143; "undecided," 2.
6. Is your sleep deep, or light? Is it easy, or difficult, to wake you? "Light," 202; "deep," 166; and 26 reported "deep sleep, but easy to wake."
7. Can you go to sleep at day-time when desired? "Yes," 103; "no," 294; "undecided," 9.
8. Are you accustomed to sleep at day? When and how long? This question was used with Nos. 1 and 2 to obtain the duration of sleep per twenty-four hours.

¹ Statistische Untersuchungen über Träume und Schlaf, von Friederich Heerwagen, in Philosophische Studien, v. 2, 1883.

III.—*Work, Disposition.*

1. When is mental labor easiest to you? "In the forenoon," 182; "late in the afternoon," 6; "at evening and night," 133; "forenoon and evening," 43; "no difference," 28.

2. What is the nature of the work? The object was to ascertain whether the kind of work limited the time of doing it, but the question was not successfully formulated.

3. Do you suffer with nervous disorders (headache, uneasiness, moodiness)? A decided "no" was given only 18 times; "seldom," 196; and "yes," 210.

4. Is your temperament sanguine, choleric, phlegmatic, or melancholic? "Sanguine," 132; "choleric," 70; "phlegmatic," 74; "melancholic," 20; various combinations, 102.

The results for the two sexes were so different that they demanded separation, while the students formed a homogeneous class interesting as a special study. The first problem that was proposed was the relation between the frequency and the vividness of dreams. It appears that 62.5 per cent of those who dream every night dream vividly, 60.5 per cent of those who dream frequently, and only 26.8 per cent of those who dream seldom, showing that the vividness of dreams increases very markedly with their frequency.

Next, how is the intensity of sleep related to the frequency of dreams? Of the students who dream nightly, 68 per cent have a light sleep (and only 28 per cent a deep sleep); of those dreaming frequently, 40 per cent; of those dreaming seldom, 32.8 per cent. Similar percentages for the other males are 68.8, 42.1, and 39.3; and for women, 72.4, 60, and 50 per cent. We conclude, then, that frequent dreams are a concomitant of light sleep, though the relation is far from universal.

These are the questions that formed the starting-point of the investigation. The rest of the information is grouped together in one large table and an admirably arranged diagram, from which more conclusions can be drawn than can find mention in this *résumé*. Those that the author singles out may be noted.

As regards sex, women have 73 per cent of their number dreaming nightly or frequently, while students have only 50 per cent, and the other males 48 per cent. Again: 63 per cent of the women sleep lightly, and only 42 per cent of students, and 44 per cent of other males. We conclude, then, that women have a very much lighter sleep than men, and that their dreams are proportionately more frequent.

Another conclusion, the evidence of which is too detailed to present, is, that as we grow older, our dreams become less frequent, but our sleep becomes lighter; age affecting the intensity of sleep more than the frequency of dreams. The author regards the students as in the period of maximum dreaming (twenty to twenty-five years of age). The deep sleep of childhood (hostile to frequency of dreams) is then least counterbalanced by the lessening of dreams due to age. The vividness of dreams shows a similar relation to age and sex: the women dream most vividly; the students, being younger than the other men, have more vivid dreams. The power of remembering dreams is also dependent upon vividness and frequency of dreaming: it is accordingly greatest in women, and greater in students than in more mature men. The liveliness of the emotional nature, a prominent feature of women and youth, seems thus to be marked out as the causative agent in the production of dreams.

The duration of sleep should naturally be related to the habit of dreaming, but in the men no such relation can be discovered. In the women, however, it appears that those who dream frequently sleep nearly an hour longer than those who seldom dream. This difference is regarded as due to the fact that men are more under duty to break short their sleep, and thus vitiate the statistics. This is corroborated by the frequency with which the men who dream frequently declare themselves tired in the morning, indicating incomplete sleep. The need of sleep is greater in women than in men: the duration of sleep being longer, and the percentage of "tired morning and evening" and of "not tired" being 3 to 2 and 2 to 3 respectively as compared with the men. Students sleep longer, and are less tired, than other men.

The time needed to fall asleep is about the same in all three classes,

—20.8 minutes for the men, 17.1 minutes for students, and 21.2 minutes for women. In each case, however, it takes longer for those who are frequent dreamers and light sleepers to fall asleep than persons of opposite characteristics. Eighty per cent of students sleep uninterruptedly through the night, 70 per cent of other men, and only 43 per cent of women. Light sleep and frequent dreams increase the interruptedness of sleep.

The power of falling asleep at will is possessed by few. It is greater in youth than in age. Twenty-eight per cent of men, 19 per cent of students, and 20 per cent of women sleep in the afternoon, indicating a making-up of insufficient sleep on the part of the men.

The effect of dream-habits upon mental work is also evident. Those who dream seldom, or sleep deeply, are better disposed for work in the forenoon than light sleepers and frequent dreamers. The forenoon seems in general to be the preferred time of work.

The statistics regarding nervousness confirm the accepted fact that this is greater among women than men. It is greater among students than among men at large. It is, too, a concomitant of light sleep and frequent dreams. As to temperament, the phlegmatic people are quite constantly deep sleepers and infrequent dreamers.

Finally, a contrast between teachers and professors of the same average age shows the effect of occupation. The teacher, with his daily toil, has a lighter sleep and more frequent dreams; while the professor, leading a comparatively congenial and worryless life, is a deeper sleeper and a less frequent dreamer. This, perhaps, is related to the lack of visualizing power that Mr. Galton found to be current among men of science.

The relation between depth of sleep and frequency of dreams seems explicable on the supposition that the insensitiveness to outside excitations present in deep sleep, also induces insensitiveness to internal impressions. The threshold of mental life is raised. If the normal psychical activity is great, then, even in a deep sleeper, will the dreams be frequent, thus accounting for the exceptions.

In addition to the interesting results that this study has brought out, it increases one's sense of the utility of such inquiries, and shows the truth of Galton's experience, indorsed by the author, that "it is a much easier matter than I had anticipated to obtain trustworthy replies to psychological questions."

ETHNOLOGY.

Jade in Alaska.

LIEUT. G. T. Emmons, who is continuing his interesting researches in Alaska, recently made an interesting find at Sitka. He writes: "A boulder of jade was dug up on the site of the present Indian village, at a depth of some three feet in loose black soil. Two pieces have been cut from it for knives or adzes, each about

20 centimetres long, from 3 to 4 centimetres wide, and from 1 to 1.5 centimetres in thickness. The three faces on which the boulder has been cut are highly polished, and show a mottled green surface, ranging in color from a yellow green to a rich dark green. After the pieces were cut down on either side, they were broken from the body of the boulder by a shock, probably by means of a wedge. On another side, where a wedge-shaped adze could be re-

moved with the least work, a cut has been commenced, forming a somewhat irregular groove, following to some extent the irregular surface of the boulder. It is 12 centimetres long, and 0.2 of a centimetre deep. From inspection, I should say it had been worked by means of a stone knife or the edge of some silicious rock not having a cutting edge of more than 2 or 3 centimetres at the greatest. The whole boulder is wedge-shaped, and 29 centimetres in length. Its weight is a few ounces less than 20 pounds. The four faces are of olive green, the more prominent rounded surfaces being veined with a rich dark green. In my collection in the American Museum of Natural History there is a small nugget about the size of a hen's egg, with a groove in it; a dark green jade; and I have also in my possession a piece of unworked jade of a rich sea-green, which I found an Indian wearing as a scratcher. It has well-rounded edges and well-polished surfaces, proving long wear. Among forty-three pieces I have collected among the Tlingit, these are the only ones that show that jade has been worked on the spot. Jade has been used for implements, generally for adzes, axes, or fighting-picks, the last mounted in wooden handles."

The finding of this boulder of jade showing 'worked' surfaces is important, as it proves that the material was found and worked in southern Alaska. It will be remembered that Dr. G. M. Dawson found a boulder of the same description on the lower Fraser River, and that Jacobsen and Dawson found boulders of this material, although the rock has not been found *in situ*. Lieut. Emmons adds that he is very hopeful of finding the exact locality from which the Alaskan jade is obtained, as he received trustworthy information referring to this interesting question from the natives.

NAVAJO INDUSTRIES. — While in former years the "Proceedings of the United States National Museum" contained almost exclusively essays on zoological, botanical, and geological subjects, in the new volume, which is being issued in signatures, much attention is paid to ethnological points. To Professor Otis T. Mason's energetic endeavors we owe some interesting notes on the methods of manufacture among the Navajo, for Dr. Shufeldt's remarks on the method of preparing deer-skins by this people was written at his instance. The most interesting portion of this essay is the description of the process of tanning, which is done by means of a decoction of brains applied to the outer side of the skin after the hair has been removed. It is said that by this process the skin attains its softness and pliability. Mr. A. M. Stephen contributes some notes on the art of shoemaking and a myth explaining certain customs connected with this art. He tells that in olden times the Navajo used to wear grass shoes, until a deity came and taught them the art of making leather shoes. As this deity's face is gray, the Navajo must avoid looking at any thing gray, — for instance, the fresh-cut edges of a skin, — and therefore the latter must always be painted red, yellow, blue, or black.

BOOK-REVIEWS.

Elements of Machine Design. By J. F. KLEIN. Bethlehem, Penn., The Comenius Press. 8°. \$6.

Gear Tables for laying out Accurate Tooth Profiles. By J. F. KLEIN. Bethlehem, Penn., The Comenius Press.

IN this work, Professor Klein, who is professor of mechanical engineering at Lehigh University, treats of the most important of the machine parts that appear in practice, giving their proportions and the main considerations governing their use and construction. The work is not, nor does it claim to be, a complete treatise upon the subject of machine design, but it is a series of notes and plates specially arranged for students of machinery desiring practice in designing the commonly occurring machine forms, and is well adapted, in extent and character, to the requirements of technical schools. It contains much that is new, including a diagram and tables for determining the diameter of stepped-cone pulleys, extensive tables of co-ordinates for laying out toothed profiles, a determination of the cross-sections of connecting-rods, and a method of finding belt-widths from their specific duty.

Pains have evidently been taken to make the work convenient for

reference. The symbols used in the formulas are placed in alphabetical order at the beginning of each chapter, which consists of a plate with its accompanying notes; the formulas are numbered; and the index is very full, being divided into four columns, referring respectively to pages, formulas, figures, and tables. To insure durability, the plates and gear tables are printed on strong bond-paper.

The first five chapters of the book are devoted to fastenings, including bolts and nuts, rivets and riveted joints, keys, and gibs and cotters. Seven chapters treat of gearing, toothed and belt. Of the remaining chapters, one each is devoted to rotating pieces, bearings, connecting-rods, and gear tables.

That portion of the book devoted to gear tables has been issued in separate form, for the use of pattern-makers, machinists, draughtsmen, and students of engineering. The tables are printed on both sides of one large card, 17 by 20 inches, so as to get them into compact form for use in the shop, draughting-room, or college. The use of the tables is made clear by examples worked out in detail, and illustrated by suitably drawn figures.

The Secret Doctrine: The Synthesis of Science, Religion, and Philosophy. 2 vols. By H. P. BLAVATSKY. New York, William Q. Judge. 8°.

THE connection between this work and science can only be shown on the Hegelian principle of the identity of contradictories; for it has not a single characteristic of a scientific treatise. It is a pure fiction from beginning to end, — a work of imagination, pretending to give an account of the creation and evolution of the world, but without even an attempt at proof. The nucleus of the book consists of some passages alleged to be taken from the "Secret Book of Dzyan," which, the authoress tells us, "is utterly unknown to our philologists, or, at any rate, was never heard of by them under its present name." And in her preface she says, "The writer, therefore, is fully prepared to take all the responsibility for what is contained in this work, and even to face the charge of having invented the whole of it." The passages from the "Book of Dzyan" are followed by an elaborate commentary; and that they need it will be evident from the following extracts, which relate to the beginning of creation: "The eternal parent wrapped in her ever invisible robes had slumbered once again for seven eternities. . . . But where was the Dangma when the Alaya of the universe was in Paramartha, and the great wheel was Anupadaka? . . . The root remains, the light remains, the curds remain; but still Oeahoo is one;" and so on for many pages.

When we inquire more closely into Mrs. Blavatsky's doctrine, we find it at bottom pantheistic. She holds to the existence of "an omnipresent, eternal, boundless, and immutable Principle, on which all speculation is impossible, since it transcends the power of human conception." Sometimes, however, she speaks as if this first Principle was the same as Space, which she calls "the seven-skinned eternal Mother-Father." To trace the evolution of the universe and of man from this first Principle is the object of this work, and is pursued through over fourteen hundred octavo pages, with more to come. We cannot undertake to give even the shortest abstract of the work, which reads like the Hindu and Babylonian cosmologies; but those who wish to see what antics the human imagination is capable of may profitably consult these volumes. There is one item, however, to which we must call attention. It seems that this occult and incomprehensible doctrine is connected with the Keely motor. We are told that there is in the universe a mysterious force capable of reducing a whole army to atoms in a few seconds; and "this great *archæus* is now discovered by, and only for, one man, — Mr. J. W. Keely of Philadelphia." It appears, however, that Keely is not destined to succeed with his discovery, because it "would lead to a knowledge of one of the most occult secrets, — a secret which can never be allowed to fall into the hands of the masses." We are also informed that "the secret teachings with regard to the evolution of the universal Kosmos cannot be given, since they could not be understood by the highest minds in this age;" so that we shall have to content ourselves with what Mrs. Blavatsky may reveal to us. The extracts we have here given, which might have been multiplied indefinitely, will give our readers a general idea of her work, and will show that whatever may be the value of her "science, religion, and

philosophy," she has at least made a considerable contribution to humorous literature.

Healing Question. By SIR HENRY VANE. (Old South Leaflets. No. 6.) Boston, D. C. Heath & Co.

The Fundamental Orders of Connecticut. (Old South Leaflets, No. 8.) Boston, D. C. Heath & Co.

THESE little pamphlets relate to the beginnings of written constitutions. Vane's paper appeared at that time in the history of the English commonwealth when serious dissensions had arisen in what he calls "the honest party," and was written with the hope of settling the difficulty. It proposed the expedient, now so familiar but then first suggested, of a national convention to prepare a constitution of government by which both people and rulers should be bound. The proposal was not acted on by the people of England, but its appearance is an event of some importance in political history. The rest of the ideas in Vane's pamphlet are those commonly held by the leading patriots of his time; and the clumsy and intricate style in which they are expressed makes the work any thing but agreeable reading. The earliest written constitution, according to Mr. Mead, the editor of these "leaflets," is that adopted by the people of Connecticut in 1638; and this constitution, with the one adopted the next year by the colony of New Haven, is here reprinted. The New Haven document is largely ecclesiastical; the Church is dealt with as well as the State, all public officers are to be church members, and in the popular convention itself all questions are settled "by sundry arguments from scripture." The Connecticut constitution is more strictly political, and its historical distinction renders it well worthy of a place in this series of popular studies.

The Seventh Annual Report of the State Board of Health of New Hampshire. Manchester, State. 8°.

THIS report of the State Board of Health to the governor and council is evidence that the year ending April 30, 1888, was an unusually active one in the State of New Hampshire so far as concerns the details of sanitary administration. A greater demand was made for the services of the board by town authorities, local boards of health, and those in charge of public institutions. In addition to this, the advice of the board was sought in hundreds of individual cases and in all sections of the State. These facts are certainly very encouraging, and demonstrate that there is a growing interest, in this State at least, in the subject of sanitation. During the year the legislature enacted a number of important sanitary measures. One of the most important of these placed scarlet-fever and diphtheria among the dangerous pestilential diseases, and gave the board authority for their suppression. Greater powers were extended to health authorities throughout the State in respect to unsanitary dwellings and polluted water-supplies.

One of the most valuable results of the board's labors is that which has come from a sanitary supervision of the summer resorts of the State. The money left by summer visitors at the various resorts aggregates several hundred thousand dollars annually; it builds homes, schoolhouses, churches, and hotels; it increases the valuation of real estate, and in many ways adds to the material prosperity of the towns, villages, and cities. The board recognizes that this great interest should be carefully guarded against the only thing that can ruin it, — disease from neglected sanitation. In the furtherance of this policy, a sewer was constructed at Rye Beach. It conveys the sewage of ten or more of the largest hotels and boarding-houses to the ocean; it is two thousand feet in length, and ten inches in diameter. Its cost was three thousand dollars.

The public water-supply throughout the State has received careful attention. Several towns have constructed water-works, and in every such instance the health of the community has been notably improved. The improvement has been especially marked in the reduction of typhoid-fever.

In the report of 1887 the board gave, in a general way, a statement of the sanitary condition of nearly thirteen hundred school-houses in the State. The surveys of these schools revealed the fact that there was no system used in their construction, and that in a great majority the plans on which they were built were such as might be devised by a carpenter ignorant of architecture and

the requirements of scholars and teachers. These buildings are not ventilated, they are inadequately heated, badly lighted, furnished with a questionable water-supply, and surrounded by foul privies. The present report deals more in detail with these defects, particular attention being given to the schools of Portsmouth and Concord.

The health laws of the State being scattered through the session laws and passed by the various legislatures, great difficulty is experienced by local sanitary officials in determining just what the law is, in reference to any given subject. To obviate this, the board has made a compilation of all such laws, and has published them as an appendix to the present report. The index to the report is very complete. Taken as a whole, this report is a valuable contribution to sanitary literature, and furnishes additional argument for those who maintain that State boards of health should exist throughout the Union, so constituted as to be as permanent as possible, and independent of politics.

AMONG THE PUBLISHERS.

THE Open Court Publishing Company of Chicago announces the appearance within the present month of an important contribution to experimental psychology by the eminent French scientist, Alfred Binet. The work is entitled "The Psychic Life of Micro-Organisms," and is published with the sanction of the author, who has written a preface especially for the American edition. The essays forming the work appeared originally in the *Revue Philosophique* of Paris, and were afterwards published in part in *The Open Court*. The original cuts have been procured, and new plates and subsequent additions to the text have been incorporated in the work. The monograph of M. Binet is a presentation of the most important results of recent investigations into the world of proto-organisms. M. Binet has added much to the psychology of the microscopic world by these researches. He has opposed many theories, confirmed others, and advanced many conclusions founded upon his personal investigation. The subject is a branch of comparative psychology little known, and, as a rule, imperfectly understood. Psychologists, and all who are interested in questions of biology, will accordingly look forward to the work of M. Binet as a welcome light on the problem of life.

—Houghton, Mifflin, & Co. will publish, about March 1, an important economic work, "Profit-Sharing between Employer and Employee: A Study in the Evolution of the Wages System," by Nicholas P. Gilman (editor of the *Literary World*). It is the first comprehensive work on industrial partnerships in our language. Written in a popular style, Mr. Gilman's work is commended as "valuable from both the scientific and the practical points of view" by President F. A. Walker, Carroll D. Wright, R. T. Ely, and other high authorities. It will undoubtedly awaken wide interest as an instructive and candid discussion of one promising method for the solution of "labor difficulties."

—The February *Magazine of American History* again anticipates the popular desire, and comes, in honor of Washington's birthday, as a "Washington number." Those who are searching for data concerning Washington's presidential career in New York City will welcome Mrs. Lamb's leading article, "Washington as President, 1789-90," a companion piece to her "Inauguration of Washington in 1789," published in December. The frontispiece represents in a group, Washington, his wife and her two grandchildren, at the age and as they appeared in 1789. The copy of Huntington's great painting of "Lady Washington's Reception" fills two full pages, and the key another page. The house New York was building for President Washington also occupies a full page. The sensational feature of the issue, however, is the De Vries portrait of Washington, discovered in Holland the past summer by the Holland Society of New York, while on its pilgrimage there. Rev. Dr. J. Howard Suydam describes the find, and gives also a picture of De Vries, the owner of the portrait. The third article, by Gen. John Cochrane, presents an unpublished letter of Washington in facsimile, written to Hon. James Duane in 1780. The four articles that follow relate to other themes, — "A Canadian-American Liaison," by Watson Griffin of Montreal; "An Oriental Account of the

Discovery of America," by Alfred J. Hill of St. Paul; "The Mound-Builders and North American Indians, whence came They?" by Jacob Harris Patton, Ph.D.; and "Slavery in New York and Massachusetts," by John Carrick of Chatham, Ont. These are followed by several shorter papers on Washington, and curious and interesting Washingtonia in the various departments.

— Mr. Andrew Lang has followed his "Letters to Dead Authors" by letters about living authors, most of them contributed to the *Independent* during the past year or two. In one of these Mr. Lang pays higher praise to Longfellow than the American Poet has yet received from any English critic. These "Letters on Literature" will be issued here shortly by Longmans, Green, & Co. Under the title of "Colloquies on Preaching," the same firm are about to publish a little book by the Rev. H. Twells on the deficiencies of the modern pulpit. The form of this discussion is quite as unconventional as its suggestions. There are about a score of pertinent dialogues in the little volume.

— *The Voice*—not the *Prohibition* organ—has changed its name to *Werner's Voice Magazine*. It is a monthly devoted to the human voice in all of its phases for speech and for song. Edgar S. Werner, 28 West 23d Street, New York, is the owner and editor.

— Messrs. Frederick Warne & Co. announce that the next volume in their Cavendish Library will be "Leigh Hunt as Poet and Essayist," being the choicest passages from his works, selected and edited with a biographical introduction, by Charles Kent.

— John Wiley & Sons, New York, announce as in preparation "A Manual of the Steam-Engine," a companion volume to the "Manual of Steam-Boilers," by Professor Robert H. Thurston; "Steam-Engine Design," for the use of mechanical engineers, students, and draughtsmen, by Professor J. M. Witham; "A Laboratory Guide in Chemical Analysis," second edition, entirely rewritten and revised by Professor David O'Brine of Colorado State Agricultural College; "A Technical Dictionary," defining as an authority all the terms of art and industry, by Park Benjamin; "The Guide to Piece Dyeing," containing 100 samples of the author's own coloring, each sample accompanied with a recipe, by F. W. Reising, practical dyer and chemist; "A Treatise on Linear Differential Equations," by Professor Craig of Johns Hopkins University; "A Treatise on Masonry Construction,"—containing materials and method of testing strength, etc.; combinations of materials, composition, etc.; foundations, testing the bearing power of soils, etc.; masonry structure, stability against sliding, overturning, crushing, etc.,—complete in one volume of about 500 pages, with 125 illustrations and eight or ten folding plates, by Ira O. Baker, C.E.; "An Elementary Text-Book of Chemistry," by William G. Mixer, professor of chemistry, Sheffield Scientific School, Yale College, New Haven; "Notes in Thermo-Dynamics and Steam-Engine Experiments," by Professor C. H. Peabody, Massachusetts Institute of Technology; "A Treatise on Hydraulics," designed as a text-book for technical schools, and for the use of engineers, by Professor Mansfield Merriman; "Brackett's Elementary Treatise on Physics," abridged from Anthony and Brackett's "Text-Book of Physics;" "Differential Equations," a mathematical treatise, specially prepared with reference to a post-graduate course, by Professor W. W. Johnson; "Kinematics; or, Practical Mechanism," Part II.,—a treatise on the transmission and modification of motion and the construction of mechanical movements, for the use of draughtsmen, machinists, and students of mechanical engineering, in which the laws governing the motions and various parts of mechanics, as affected by their forms and modes of connection, are reduced by simple geometrical reasoning and their application is illustrated by accurately constructed diagrams of the different mechanical combinations discussed,—by Professor Charles W. MacCord, Stevens Institute of Technology; "Preparation of Organic Compounds," introduction to the preparation of organic compounds, by Dr. S. Levy of the University of Geneva, translated and revised by Professor P. T. Austen, Rutgers College, and New Jersey State Scientific School; "Flow of Water in Rivers and other Channels," by Ganguillet and Kutter, translated, revised, and extended by Rudolph Hering and J. C. Trautwine, jun.; and "A Grammar of the

Hebrew Language," greatly enlarged, and for the most part rewritten, by Professor W. H. Green, D.D., Princeton Theological Seminary.

— In the *St. Nicholas* for February, Noah Brooks's account of "The White Pacha" tells the narrative of Stanley's past achievements and probable whereabouts. The paper is illustrated by a striking portrait of the great explorer, and will give many of the older readers of the magazine their first clear idea of the state of affairs in Central Africa. A well-illustrated article upon Japan follows, and is contributed by Arthur L. Shumway; and this, with Mr. Alton's explanation of "The Routine of the Republic," makes up the list of the more instructive articles of the number.

— In *Outing* for February we note the following principal articles: "Sleighting," by Will. H. Whyte; and the second of the series of papers on "American College Athletics—Yale University," by Richard M. Hurd. This article is richly illustrated, as is the description of "A Russian Wolf-Hunt," by Tom Bolton. In addition, we note Charles Lee Meyers's account of the Jersey City Athletic Club; an entertaining description of "A Trip across Wyoming on Horseback," by L. P. Robie, illustrated by E. W. Deming; and "Herne, the Hunter," a tale of mountain life, by W. Perry Brown. The "Editorial Departments" are attractive, while the "Records" present the latest achievements of athletes in the different sports and pastimes.

— Assistant Superintendent N. A. Calkins of New York City, so well known by his books on "Object-Teaching," has in press a little volume for teachers on "Ear and Voice Culture," to be published by E. L. Kellogg & Co. of New York and Chicago.

— "Easy Experiments in Science," is the title of a little handbook by Professor J. F. Woodhull, formerly of the normal school at New Paltz, N.Y., to be published in February by E. L. Kellogg & Co., New York and Chicago.

— There is a timeliness in several of the articles in the February *Atlantic*. "The New Talking-Machines" is the subject of an article on the phonograph by Philip G. Hubert, jun. Charles Worcester Clark discusses "The Spirit of American Politics as shown in the Late Elections." A feature of this number is the address to the assembly at the opening of the new Players' Club in New York, by T. W. Parsons, which became the special property of *The Atlantic*, and which is now for the first time published. In sharp contrast with this witty and cheerful poem, Henry C. Lea writes on "Brianda de Bardaxi," describing one of the fiendish devices of torture devised during the time of the Inquisition; Agnes Repplier, one of the brightest essay-writers in America, contributes "A Plea for Humor;" Harriet Waters Preston, in an article entitled, "Under which King," paints in glowing colors certain passages in the life of Cicero; and Samuel H. Scudder finds a congenial topic in "Butterflies in Disguise." The prominent reviews are on the "Letters of Felix Mendelssohn," "Ancient Rome in the Light of Recent Discoveries" (the Lanciani book), and "Illinois Life in Fiction." Some rather quaint points are raised in "The Contributors' Club;" and "Books of the Month" is, as usual, readable and entertaining.

— It is worthy of note that editions of every important book published here by Charles Scribner's Sons in the past season have been printed in England.

— The Travellers' Insurance Company will publish at once, in five octavo volumes, a uniform edition of the works of Walter Bagehot, the economist.

— Macmillan & Co. will shortly publish an American novel on the subject of divorce, entitled "Faithful and Unfaithful," by Miss Margaret Lee.

— The Forest and Stream Publishing Company announces "Sam Lovel's Camps," a sequel to "Uncle Lisha's Shop," by Rolwand E. Robinson. It is descriptive of Vermont life and character forty years ago.

— C. Wellman Parks, of the Rensselaer Polytechnic Institute, Troy, N.Y., has undertaken the preparation of an exhibit of American periodicals for the Paris Exposition of 1889, and requests all interested to help him make it complete and worthy.

LETTERS TO THE EDITOR.

Indian Relics from North Carolina.

DURING the past summer the writer was one of a party who tramped through the mountains of western North Carolina for a month. The country was extremely rough, and we were somewhat surprised at the exceeding abundance of Indian relics. Arrow-heads were found almost everywhere, and we often picked them up even in the roads. There was hardly a mountaineer to be found who had not at least a hatchet or a scraper, and often a native would come in smoking a pipe he had found in his cornfield. The favorite material for the pipes and scrapers was soapstone. Some of the former resembled in shape the common clay-pipe bowl;

FIG. 1.

and it is possible that such are recent, for it is not more than forty or fifty years since the Cherokees roamed over all that region. Still we saw none such among the Indians on the Reservation, and of many of the relics they know as little as we. The hatchets were of a variety of materials, and none of them highly polished.

In almost every cornfield the soil was filled with fragments of pottery, some solid and showing marks of fire, others crumbling to dust. One could pick up pieces by the thousand, and not one could be found which did not show some form of ornamentation. All the designs were geometrical figures formed by combinations of straight lines and curves, both circular and spiral. The edges of the vessels seemed in some to be plain, and in others raised and scalloped or notched. None were found showing any traces of

FIG. 2.

handles, or any lines of chafing from cords. The designs were evidently made with a sharp point while the clay was soft. The Cherokees still make much of their own pottery, but it is rude, and as a rule unornamented.

We ran across several specimens which puzzled us. One, which is represented in Fig. 1, was shown to us by the owner of a gold-mine near Cashiers Valley, Jackson County. It was washed out in the gravel. We were permitted to make a drawing of it. It is neatly cut from a greenish soapstone, and is quite smooth. It is badly broken, but the apparent form is indicated by the dotted line. It resembles somewhat one of the old-fashioned sugar-loaf hats, and is neatly hollowed out on the inside. Nearly in the middle of the side, as will be seen from the drawing, is a small hole drilled through the stone. We could think of no possible use for such an implement.

Another interesting one, found in a field near the Nautehala Mountains, in Macon County, is shown in Fig. 2. It is an oval block of soapstone, with perfectly flat ends, and has in one end a

neatly cut circular hole 1.5 centimetres in diameter, and 2.3 centimetres deep. The length of the specimen is 9.7 centimetres, and its greatest breadth 8.5 centimetres. The surface is comparatively smooth, but no attempt seems to have been made to polish it. It is now in the possession of the writer, who would be glad to receive any information as to its use.

The only mound we saw is close to the town of Franklin, the county seat of Macon County. This stands on the bottom-lands, not far from the Tennessee, and is well preserved. It is an oval truncated cone; and we estimated the greatest diameter of the base at seventy-five feet, and its height at twenty feet. We heard of another on the road from Charleston to the Indian Reservation at Yellow Hill, but failed to find it. Beads, arrow-points, pottery, and other relics, are often ploughed up near these mounds, but the limited time at our disposal prevented any very thorough exploration.

L. N. JOHNSON.

Evanston, Ill., Jan. 19.

The Characteristic Curves of Composition.

I WAS intensely interested in the article *Science* published more than a year ago, by Professor Mendenhall, on style curves, and made up my mind to submit the Bacon-Shakespeare question to a style-curve test at once. But somehow it was only last week that I

got at it. I enclose you the result. The light line is Bacon; the heavy, Shakespeare.

In order to understate it, if possible, I selected the Shakespeare from Oliver's speech (*Twelfth Night*, II. i. 110), — a passage almost as sententious as Bacon's acknowledged work; and the Bacon from his "Essay on Youth and Age." APPLETON MORGAN.

New York, Jan. 10.

The Permian Rocks of Texas.

As it is evident that the question of the occurrence of Permian strata in America will again be raised at an early day, and that generalizations will be based upon the as yet little studied Texas region, it may be in order to state that we have here a great series of beds, beginning west of the 97th meridian, and succeeding the carboniferous; and beneath the undoubted Wealdan beds of the cretaceous, a great development of strata, the lower half of which cannot possibly be referred to any other age than the Permian, although the upper portion is probably triassic. Professor Cope has long since described the vertebrates of these Permian beds; and the *Mollusca*, I am informed, are now being examined. The stratigraphy, however, has as yet only been reconnoitred, and no section whatever determined. The writer, however, made two journeys across the region into New Mexico last summer, to observe the problem, and was impressed with a fact which should be borne in mind in future discussions of the region. The stratigraphic features agree, as far as could be seen, in nearly every generality with those of the Kanab Valley of Utah as described by Mr. C. D. Walcott, a few years ago, in the *American Journal of Science*, and were the direct eastward continuation of the same. Not only does this similarity agree with the Permian beds, but with the upper beds, which he calls triassic. This connects the Grand Cañon and Texas Permian-triassic basin beyond all doubt; and to Mr. Walcott belongs the credit of the first and only intelligible section of the American Permian, a most marked and unmistakable terrain, the discovery of which was made, as agreed, by Professor Jules Marcou. This fact, together with the distinct basin type of structure of the trans-Pecos region, to which I have recently called attention, and the determination of many distinctly western geographic features extending two-thirds the way across Texas, makes this State pre-dominantly western, although its eastern third is within the limit of the timber-covered southern coastal plain.

MAX O'RELL'S
IMPRESSIONS OF AMERICA.
**JONATHAN
AND
HIS CONTINENT**

RAMBLES THROUGH AMERICAN SOCIETY
BY
MAX O'RELL,

Author of
"John Bull and His Island," "John Bull, Jr.,"
etc., etc., and
JACK ALLYN,

Translated by Madame PAUL BLOUET.
In one elegant 12mo volume. Price, \$1.50.
Max O'Rell, in this volume of impressions of
America and the Americans, gives us the brightest
and best work he has yet done. While often severe,
he is always kind. Altogether the book is very
lively reading and will unquestionably excite the
interest of every American citizen who wants to
know what a keen-eyed, intelligent, and witty
Frenchman has to say of him and of his country.

Insurance.

DELAY IS DANGEROUS.

We call attention to the new form of Accident (indemnity) Insurance policies, which are written by the Merchant's Casualty Insurance Association, 21 Park Row, New York City. John S. Purdy, Secretary. These policies cover weekly allowances of from \$10 to \$25, according to occupation, at a cost of only \$6 a year exclusive of the cost to join, which is \$5 payable once only. The public, as a rule, carry life insurance, and the ordinary accident policies issued by companies, paying a sum in case of death, is not so desirable as one of these indemnity policies in case of accidents, which are so plentiful in this fast age with its railroad horrors, fast driving, electric wires and other countless forms of danger which the public is constantly exposed. The fact of the Association having no unpaid claims, and its having just passed an examination by the Insurance Department of New York State, shows that the management is liberal with its policy-holders and conservative in its action. The Association also desires to secure energetic Agents in every village and town, to whom territory and favorable terms will be given.

What Scott's Emulsion Has Done!

Over 25 Pounds Gain in Ten Weeks.
Experience of a Prominent Citizen.

THE CALIFORNIA SOCIETY FOR THE
SUPPRESSION OF VICE.
SAN FRANCISCO, July 7th, 1886.

I took a severe cold upon my chest and lungs and did not give it proper attention; it developed into bronchitis, and in the fall of the same year I was threatened with consumption. Physicians ordered me to a more congenial climate, and I came to San Francisco. Soon after my arrival I commenced taking Scott's Emulsion of Cod Liver Oil with Hypophosphites regularly three times a day. In ten weeks my avoirdupois went from 155 to 180 pounds and over; the cough meantime ceased. C. R. BENNETT.

SOLD BY ALL DRUGGISTS.

SCIENCE

FRIDAY, FEBRUARY 8, 1889.

THE THORNE TYPE-SETTING MACHINE.

It is nearly ten years since Mr. Joseph Thorne invented the type-setting machine bearing his name. This machine, as now manufactured by the Thorne Machine Company of Hartford, Conn., modified by the improvements suggested during several years' act-

der. The types, before distribution, are arranged in vertical channels in the upper cylinder, where they rest upon their sides. The distributing-cylinder revolves with an intermittent motion, thereby causing its channels at each step to coincide with and rest directly over similar channels in the setting-cylinder, which remains stationary.

Ordinary fonts of type are used, but each character has distinctively arranged notches, with which correspond wards at the upper

THE THORNE TYPE SETTING AND DISTRIBUTING MACHINE.

ual use in type setting and distributing, is shown in the accompanying engraving. This machine is now doing good service in book and newspaper offices in this country and Europe. Its working, as seen by a representative of *Science* a few days ago in an office in this city, where several of them have been in use some years, leaves little to be desired in the way of rapid and accurate distribution and composition.

The machine consists of two iron cylinders, mounted vertically one above the other upon the same axis. The upper one of these two is the distributing-cylinder, and the lower one the setting-cylinder

of each channel in the setting-cylinder; so that a type of a given character can only fall into its own proper groove in the latter. In these grooves the types rest on a bottom plate. The types in the distributing-cylinder are in the order they come from the forms; but by the step-like motion of the cylinder, and the action of the wards in the channels of the setting-cylinder, the types are automatically sorted, so that each channel of the stationary cylinder contains only types of the same kind.

Composing is effected from a keyboard like that of a type-writer, on a somewhat larger scale. By the depression of any key, through

an arrangement of levers and rods, the lowest type in the corresponding groove of the composing-cylinder is pushed radially outwards on to a very rapidly revolving disk, which carries it to an opening in the stationary guard surrounding the disk, and delivers it upon a moving belt, on which the types are carried in their proper order to a revolving lifter, which raises them in succession into a long setting-stick in front of the operator, terminating in a justifying-stick at the upper end of an inclined channel or galley.

In justifying, a section of the composed line of type is drawn to the mouth of the justifying-stick, and is justified with spaces taken from a case containing channels for the different spaces and the hyphen, the lowest of which are pushed partially out by ejectors worked with a treadle.

The lines of type, when ready for distribution, are inserted in the grooves of the distributing-cylinder from a special galley by means of a slide, with which a whole line at a time is pushed bodily into a groove.

It is claimed that this machine will distribute and set at the rate of six thousand ems per hour, doing, with three persons, the work of six men working in the ordinary way. Considering the purpose for which the machine is intended, the construction is simple, and there appears to be no difficulty or hitch in the working.

It should be remarked, that, by manipulating the keys in one direction only, several keys may be touched simultaneously without risk of the characters becoming transposed. In working the opposite way, each key must be touched separately. The machine is driven from a shaft by two small belts. One belt transmits motion to the revolving disk below the type-setting cylinder and to the type-lifter; while the other belt, by means of a tightening-pulley and ratchet-gear, produces the step-by-step motion of the distributing-cylinder.

THE STEAM-ENGINE, ITS PRINCIPLES, ITS DEVELOPMENT, ITS PRESENT CONDITION, AND ITS FUTURE PERFECTION.¹

In this lecture will be found, stated in a very compact form, the fundamental principles of the steam-engine, and a history of its development. Some of the statements at first glance seem very startling, but they are so supported by the records that surprise is overcome by conviction. One of these statements is, that "for a generation after James Watt's death the art of producing power from fuel by the intervention of a steam-engine retrograded; so that less power was usually obtained from a pound of coal consumed than had been obtained by the use of methods invented and fully explained by James Watt."

This is illustrated by the following: "Founded upon these principles, the steam-engines which were made by Mr. Watt and his associates and pupils before 1830, produced a horse-power with less than two pounds of coal an hour. These engines are known as the Cornish pumping-engines; and, if you will look into the history of these machines, you will find them reported as doing more than a 'hundred millions of duty,' which is a technical phrase, intended to express the fact that a hundred million pounds of water were lifted a foot high for a hundredweight of coal consumed. Turning that into horse-power, it means about two pounds of coal an hour a horse-power. This result was produced by cutting off steam in the cylinders at one-sixth or one-eighth of the stroke, and allowing it to expand six or eight times. The engines of that day, of course, were very imperfectly constructed, and great losses occurred from leaking pistons and from defective boilers; but, notwithstanding that loss, the result was equal to two pounds of coal an hour a horse-power."

In a note on the subject, reference is made to the authorities showing the "duty" of Cornish engines before 1830 to be more than a "hundred millions," or, what is the same thing, a horse-power with less than two pounds of coal an hour. Perhaps the contrast between the engines did not attract much attention, because the Cornish engine's economy was always stated in terms of weight lifted, whereas economy in other engines was stated in terms of coal an hour a horse-power.

¹ Abstract of a lecture delivered by Edward N. Dickerson, LL.D., before the Electric Club of New York, Jan. 17, 1889.

The lecturer, on this subject, makes this statement: "When steamships came to be built in England in 1840, and afterwards, notwithstanding the fact that high expansion with great economy was in constant operation on James Watt's Cornish engines and on Wolff's compound engines, no attempt was made to work the marine engines under high expansion; and as a consequence all the earlier steamships, for more than thirty years, were running at a cost of at least four pounds of coal an hour a horse-power; while, at the same time, compound engines had been well known for a generation, and were in actual use, making a horse-power for about two pounds of coal an hour. The Cunard Company, however, were making money in their business; and they considered that a sufficient answer to any suggestion that their fuel account was enormously expensive."

It is certainly a very remarkable fact that for a generation steamship-owners did not use high expansion on their ship-engines, when it had been in use on shore for thirty years, both in single and in compound engines.

The fact, perhaps, is not generally known, as stated by the lecturer, that "in 1825 several steamboats on the North River worked by double expansion engines, were built by Mr. Allaire, in this city, — the 'Henry Eckford' for one; and the 'Sun,' which made the trip to Albany in about twelve hours, for another. At that time the subject was not well enough understood, and economy in fuel was not considered of so much consequence as the first cost of construction, and these engines were not largely reproduced. One of these double expansion engines made in England was brought to this country in 1830, and for many years was used in the oil-factory of Judd's Sons, giving very economical results. When they needed more power, a half-stroke cut-off engine was made for that factory and added to the other, but its results were vastly inferior to that of the compound engine."

The explanation is probably the true one, that the greater original cost of compound engines was of more consequence in those days than subsequent economy; and so the compound engines were neglected and lost sight of, till attention was again called to them by Mr. Jameson in 1860, when it was necessary to save a steamship company on the Pacific Ocean from ruin, because of the high cost of fuel there; and he adopted the very obvious remedy of reducing coal-consumption one-half by the use of the old compound engines, which had been disregarded for years.

One very interesting fact brought prominently forward is thus stated: "The astonishing fact exists to-day, that, on an average, every steamboat running on the waters of New York is wasting certainly not less than fifteen per cent of all the fuel consumed, by leaking through the valves; and almost any one of them will run at the rate of four or five miles an hour without ever opening the steam-valves at all, and simply by the leakage through those valves; and yet that leakage is only the difference between what leaks in through the steam-valves and what leaks out through the exhaust-valves. Some of these steamboat-engines are so constructed that the engineer can 'unhook' the steam-valves without unhooking the exhaust-valves; so that, as the engine moves, the exhaust-valves are working, and the steam-valves are shut. That is particularly true of some of the steamboat-engines on the New Haven line; and when the pilot rings the slow-bell, as he frequently must do in going through the crowded thoroughfares, the engineer simply unhooks the steam-valves and lets them drop shut, and the steamboat moves on at a fair rate of speed from the leakage alone; whereas, if those steam-valves were tight, the engine would be stopped in half a revolution. This tremendous loss is not appreciated, because it is a case of internal hemorrhage, and no visible sign appears. The steam leaks into the condenser, and is pumped overboard with the condensing water; but, as far as I have observed, it has not raised the temperature of Long Island Sound at all, and therefore has not produced any effect on climate; and there is no advantage gained by that tremendous expenditure. The remedy, of course, is very simple, and that is to go back to James Watt, which would mean at least fifteen per cent of saving in the coal-bins."

A note very fully explains how this loss occurs, and why it escapes observation. All the earlier steamboats used the single puppet-valves of James Watt, which are necessarily perfectly tight

when once ground into their seats; and, as they are forced into their seats by the pressure of steam, it is impossible for them to leak. But, being heavy to lift by hand, some one invented the double-balanced valve, in which the steam is pressing upward and trying to open the lower of two valves, while it is pressing downward on the upper one; so that there is no trouble in opening them by hand. Of course, such an arrangement must leak; and, when steam once begins to leak, it cuts its way through the crack, and very soon has an open passage.

It has not, however, been supposed that the leak was so enormous as stated; but the lecturer appeals to what he says are facts within his knowledge, and which are easily verified any day. If it is true that steamboat-engines will run the boat without opening the steam-valves, as he says, and that it is done as a practice on some East River steamers when the engine is required to go slow, it is certainly most astonishing that owners should permit such a state of things to continue for a day. As the lecturer says, it is a case of internal hemorrhage, where the patient may bleed to death without knowing the cause.

The lecture contains two cuts, exhibiting the single puppet-valve of Watt, and the double or balanced American valve, as below.

It is very apparent from the sketch that the double valve must be leaky. The pressure upwards on the lower valve

JAMES WATT'S SINGLE PUPPET-VALVE.

AMERICAN BALANCED PUPPET-VALVE, WHICH MUST LEAK 15 PER CENT OF STEAM USED BY ENGINE.

balances the pressure downward on the upper one, and of course the valve opens easily; but unless the upper and lower valves, which are rigidly separated by a column, can be fitted at exactly the same distance apart that the seats are, of course they must leak, since no pressure can take effect on either to force it into its seat. If they could be so perfectly constructed as to be steam-tight when cold, the moment they are heated by steam, the expansion of the column must differ from that of the enclosing chest, and at once a leak begins; and when it does begin, it soon cuts away the metal.

The lecturer takes up the present theory that great losses are incurred in working steam expansively, according to the laws of Watt, by what is called "cylinder condensation," which is said to destroy as much as one-quarter of the steam introduced into the cylinder, and to that extent neutralizing the theoretical gain by expansion. This hypothesis was put forward by the engineers of the navy in 1860, as the true explanation of a very common fact, that a steam-engine does not give out power in proportion to the expansion used. This explanation was supported by an experiment tried by the United States on an engine on Lake Erie, to which the lecturer refers as follows:—

"In the history of the development of the steam-engine, one cu-

rious phenomenon deserves to be mentioned, and that is the attack upon James Watt and his laws of steam by the Government of the United States during the Rebellion, when vast sums of money were expended in building steam-engines. At that time the Government officially pronounced its judgment of condemnation upon the laws of Watt, and published that judgment in a book, which was distributed to the engine-builders and engineers of the country as the authoritative decision by the United States. This absurd conclusion was reached in consequence of some experiments ignorantly tried by some Government engineers, on a leaky engine on Lake Erie, which, as the report showed, was using more than twice the fuel to the horse-power that James Watt's engines were using. What was proved by the experiment was, that such a machine as that was not a good one to make forty-seven horse-power by expansion; but it was assumed that it proved there was no use in expansion. I quote from that book the following:—

"The results obtained from this engine (that is, the Lake Erie engine) are rigorously applicable to all others in which saturated

steam is employed in a cylinder not jacketed, and, show conclusively the utter futility of attempting to realize an economical gain in fuel, under such conditions, by expanding the steam beyond the very moderate limit of one and a half times; and that, if the expansion be carried to three times, a positive loss is incurred; also that if measure of expansion, as high as those due to cutting off the steam at $\frac{1}{4}$ or $\frac{1}{8}$ of the stroke of the piston, are employed, the economy is considerably less than with steam used absolutely without expansion."

"Upon that principle, the whole steam navy of the United States that was built during the war was constructed. This was a tremendous blow to progress, from which we have not yet entirely recovered; and but for the fact that the engineers of Europe have since built their magnificent steamers, and carried expansion to a high degree, we should have been building a navy to this day in accordance with this ignorance. But James Watt, for a dead man, made a magnificent fight in defence of his principles; and the money and resources of the United States have utterly failed to defeat him."

In an elaborate note, an explanation is made of the way in which this remarkable conclusion was reached, supported by the tabulated report on which it was supposed to rest. As the table shows, the "Michigan's" engine was run at various rates of expansion, beginning at nearly full stroke, and running down to a cut-off at one-eleventh of the stroke, — the pressure of the steam being kept constant, and the revolutions of the engine kept the same, by taking off resistance, — so that at full stroke the engine developed 280

net horse-power, and at one-eleventh of the stroke only 47 horse-power, and in that proportion. Each experiment lasted seventy-two hours. The water was carefully measured as it was taken into the boiler; and the steam which resulted from that water was estimated from the indicator diagrams as it went into the condenser. The result of these trials is thus stated in a note, quoting the figures from the report:—

"In round numbers twelve hundred pounds of water an hour disappeared from the engine, whether the steam followed the piston full stroke, or was cut off at one-eleventh of the stroke; and, of course, the expansion rate had nothing to do with its loss. Indeed, at the high expansion there appeared less loss of water than at lower rates. The fact, of course, was that the double-balanced puppet-valves of that engine leaked about the same amount of steam into the condenser an hour when the engine was running, and it made no particular difference whether the cut-off was long or short.

"If the estimated water in steam, as shown by the indicator, could have been ascertained as accurately as the water pumped in was, it would have appeared that at the high rates a still smaller loss occurred than the tables show, as compared with full stroke; because, after the cut-off valve shuts, the steam-pressure falls off in the cylinder, and less steam ought to leak into the condenser than if the boiler-pressure were kept up in the cylinder during its entire stroke; but these indicator measurements cannot be exactly accurate. They, however, established the fact that in this case high expansion destroyed less steam than full stroke, and so completely demolished the theory which the experiment was tried to establish. That, however, did not prevent the forcing of balances, and other similar manipulation of the honest figures, in order to prove the hypothesis under which the experiment was tried; and the result was announced that the Lake Erie experiment had proved what it was intended to prove, and the official United States Government report was issued to the world, announcing the new discovery.

"If book-keeping could have beaten James Watt, he and his laws would have perished from the earth; but, as it was, they were only driven for a season out of the American Navy."

It is not important for science to know whether the conclusion drawn from the facts was fraudulent, as the lecturer asserts, or simply a stupid blunder. The fact is, that an almost constant quantity of steam disappeared from the engine in an hour, under all circumstances, and of course its loss had nothing to do with expansion. The quantity—twelve hundred pounds an hour—was a very large percentage of 47 horse-power, and a small percentage of 280 horse-power; and this fact was put forward as proving that expansion destroyed a much larger amount of steam used than full stroke did, whereas in fact a trifle less steam was destroyed when high expansion was used than at any other time.

The explanation, open to any one's verification by the tables themselves, disposes of this extraordinary trial, and destroys the theory based upon it. It is great service to truth to make this exposure.

The lecture ends with this expression of opinion:—

"It is my opinion, that, with our present knowledge of machinery, a steam-engine can be built to day that will produce a horse-power with three-quarters of a pound of coal an hour, if of sufficient size to reduce the percentages of loss by radiation, friction, and leakage, to a minimum. Under those circumstances, your fuel expense would be less than one-third of what it now is."

It would seem that there should be some means of bringing this to a test. No one claims at present less than a pound and a half an hour in the most elaborate and extensive steamers; and, if this opinion is correct, half the coal now used, or a power double that now got from the same fuel in the most perfect machine, would be the result of such an engine.

In a review we cannot go over the whole ground on which the lecturer places the case; but to those specially interested in the subject there is matter enough for very serious consideration, and we commend the paper to their notice.

SETH K. WARREN of Geneva Lake, Wis., publishes a little volume devoted to the "Evolution Theory of the Origin of Worlds."

IMPROVED GASLIGHT.

NOTWITHSTANDING the rapid development of the electric-light industry, gas still remains the most widely used and convenient illuminant; and any means of improving the quality or decreasing the cost of gaslight is of interest to the public. One improvement in both these features, now attracting much attention, is known as the "albo-carbon light."

In this light the ordinary illuminating-gas is passed through a simple apparatus, in which it is enriched by taking up a hydrocarbon vaporized by a current of heated gas. It is claimed by the company who have introduced it to the public that one thousand feet of common coal-gas, after being passed through their appliance, will give fully as much illumination as three thousand feet where ordinary burners are used; in other words, the cost of illumination is reduced to at least one-half, while the light is far more satisfactory. The apparatus can be attached to any ordinary gas-pipe or gas-fixture in a few minutes, and no change in the meter or

THE ALBO-CARBON GAS-FIXTURE.

gas service is required. The carburetting vessel is detachable, and may be readily removed from the fixture for refilling with "carbon." This operation is quickly performed, and the whole appliance is so simple that it requires practically no attention. There is no complicated mechanism, and consequently nothing to get out of order.

The adaptability of this light for illuminating purposes under all circumstances is proved by the fact that it is now in use in many of the largest business-houses in this city and Brooklyn. Professor Stevens of Girard College, Philadelphia, says of it, "I have tested the albo-carbon light. . . . The burner consumed 2 cubic feet of gas per hour. One foot of common gas per hour equalled 2.5 candles, while one foot of the gas when carbonized equalled 8.125 candles. Regarding candle-power, the carbonized gas is equal to 3.25 times the common gas. Comparing the common gas with the standard 5-foot Argand burner, 5 feet per hour with the Argand burner equalled 17.20 candles; 5 feet of carbonized gas equalled 40.625 candles, which is 2.36 times the candle-power of the standard Argand. . . . The perfectly steady, soft light furnished by the albo-carbon burner adapts the light admirably for reading, for manufacturing establishments especially, and for general household uses."

The tests referred to above refer only to single lights: when the

alco-carbon light is burned in clusters of burners, a much more striking effect, with a far higher result in lighting-power, is produced. An eight-light cluster tested on London 16-candle gas gave 8.84 candles per cubic foot, while with the larger clusters the increase in candle-power is still greater. This light may be seen in use every evening at 728 Broadway, this city, the office of the Alco-Carbon Light Company.

THE NEW WESTON VOLTMETER.

It is a law of human progress, nowhere better exemplified than in the industrial and mechanic arts, that all systematic and permanent advance depends upon our ability to determine quantitatively, in terms of some standard, the value of the various factors involved in any given operation or transformation. An idea of the crudeness of men's notions of measurement in former times as compared with the present, may be gained from the names of units or stand-

ard the elimination of guesswork and the substitution of knowledge. Engines, dynamos, batteries, electric motors and lamps, are sold with a guaranteed efficiency and life, subject, however, to definite conditions as to use. It is generally because of the absence of definite knowledge as to when the imposed conditions are actually observed, that losses so frequently exceed profits. When measurements of the value of electrical appliances are actually made, the results are often discredited because of doubt as to the accuracy of the instruments used, and probably the general indifference to accurate work manifested by many electricians may be justly ascribed to the absence of reliable measuring instruments.

Most of the commercial electrical measuring instruments in use in this country to-day are of foreign manufacture. They may be briefly described as either of the permanent or electro magnet type. The former are in general disfavor, and unjustly so, because their defects are not inherent in the types, but are, rather, the natural result of poor design and construction. Those who have had much

FIG. 1.

ards which have been handed down to us. Thus three barley-corns made one inch, the foot was the length of the king's pedal extremity, the hand is a measure still in use in estimating the height of horses, etc. Compare such notions with the accuracy required in modern machine-shop practice. It is, in fact, only when the value of work already done becomes known, that one is prepared to make further progress, as every step in advance demands increased refinement in the means and methods of measurement. As an instance in point, witness the mutual development of the steam-engine and the steam-engine indicator. Just as the indicator has advanced to a state of perfection such that its records are universally relied upon to detect faults in present apparatus, and intelligently outline the direction of improvement, so has there been a gradual advance in the construction of commercial electrical measuring instruments, serving a similar purpose, and tending to effect a similar result, in electrical engineering.

While it is true that thousands of engines are never indicated, and thousands of electrical appliances are never carefully tested, it is equally true, as a consequence, that useful energy is wasted, property destroyed, and money lost.

In electrical as well as in mechanical engineering, success neces-

sary experience with these instruments, of which the Deprez and Ayrton & Perry are examples, will recognize the fact that while these instruments are new, they are subject to rapid and serious changes in their constant. The rate of change, however, diminishes with age and use, up to a certain period, when they assume a condition of stability, and are thenceforth, in so far as the controlling force is concerned, reasonably reliable. Uncertainty as to when this condition of stability is attained necessitates frequent calibration, and is thus a serious obstacle to accurate work. A second defect is the heating error introduced when the instruments were kept in circuit even for the short time necessary to make readings.

Instruments of the electro-magnet type are, on the other hand, more generally in demand, because of the prevalent idea that they are not subject to errors arising from a variable controlling force. Errors, however, fully as serious as have been ascribed to permanent magnets, are not only common, but seemingly inherent, in this type, because of the magnetic persistency of the softest iron, even when subdivided. This error is most noticeable when readings are made with a rising, succeeded by a falling current, and often amounts to as much as twenty-five or thirty per cent. The best forms of this type of instrument are, perhaps, the ingenious

spring voltmeters and ammeters of Ayrton & Perry. These are, however, subject to serious heating and frictional errors.

Thus far we have mentioned only the most glaring defects common to commercial instruments. Another and almost universal defect is due to inaccuracies in the reading-scale. A great advance was certainly made when direct-reading instruments were substituted for those requiring a multiplying constant. It is a notable fact, however, that most of the direct-reading instruments, judged by the uniformity of their scale-divisions, follow the proportional law. This is extremely doubtful, however, and calibration generally reveals the fact that seldom are there more than two or three of the scale-marks correct. Printed or engraved scales may justly excite suspicion as to their accuracy.

The advent of an improved type of commercial electrical measuring instruments for direct-current circuits, in which the sources of error enumerated above are practically eliminated, and which are equally well adapted for both laboratory standards and commercial service, is justly to be regarded as an important step in the develop-

nary use, is now generally acknowledged. In these instruments special care has been taken not only in the selection of steel and its proper magnetization and artificial aging, but the magnetic resistance of the acting field has been reduced to its lowest practical limit by the insertion of a central core of soft iron within the movable coil. This core is supported upon the magnet frame by a strap of diamagnetic material. The form of the pole-pieces is such that the deflecting coil constantly moves in a uniform field, and hence the deflections practically follow the proportional law; and a direct-reading scale, of nearly equal subdivisions, is obtained. The movable coil is wound upon a light frame of copper, which serves the double purpose of a support, and also, since it moves in an intense field of force, as a damper, thus making the instrument exceedingly dead-beat.

All of the more important parts of the instrument are made to gauge, and the bearings of the deflecting coil are jewelled. Interchangeability of parts, and the elimination of friction, are thus obtained. A difference of potential of about one and one-quarter

FIG. 2.

ment of electrical engineering. The Weston Electrical Instrument Company of Newark, N.J., have recently placed upon the market a new form of commercial voltmeters and ammeters, designed by Edward Weston, the well-known electrician. The especial aim in designing these instruments has been not only to entirely eliminate such variable factors as have been enumerated above, but to add to the instrument certain valuable features mentioned below. To this end, the electrical, magnetic, and mechanical features have been so worked out as to insure permanence and reliability, coupled with simplicity, extreme accuracy, a wide range of scale-reading, and portability. The accompanying engravings (Figs. 1, 2, and 3) give general and detailed views of the voltmeter. It will be seen that the field of force is produced by a permanent magnet of peculiar form, while the deflecting body, carrying the index, is a light coil of insulated wire, whose motion, resulting from the dual fields established by the magnet and current circulating in the coil, is restrained by two coiled springs. The springs serve also to convey the current into and out of the moving coil.

That permanent magnets can be, and in fact are, daily made, which, after undergoing a process of artificial aging, remain thenceforth practically constant in strength when subject to ordi-

navolts, at the terminals of the movable coil, serves to deflect the index over the entire scale, the length of the scale being about six inches. This degree of sensitiveness permits, therefore, the construction of instruments having a wide range of maximum scale-reading by the simple insertion of differentially wound resistance-coils, in series with the movable coil.

Figs. 1 and 2 exhibit the external and internal parts respectively of the new voltmeter, having a scale of double values, with a ratio of 20. The scale divisions for the upper values (Fig. 1) are single volts, while for the lower values they read one-twentieth of a volt. The single divisions are of such a size that one can easily read to one-tenth of a division; namely, to one-tenth of a volt on the upper values, and one two-hundredth of a volt on the lower. This form and ratio of scale values is useful for battery-work, and especially for storage-batteries. The lower scale values are used when examining single cells, or sets of two; and the upper scale values, when measuring the aggregate potential difference of a series of cells. In the former case, connection is made with the small binding-post (under the rubber cap) on the left, and with the larger binding-post on the right. In the latter case, connection is made with the two large binding-posts.

Another very important feature is the means afforded those not in possession of laboratory appliances of verifying the scale value by applying a single cell of some constant form, such as is to be found in any telegraph-office, to the terminals of the coil giving the lower scale-reading. The deflection noted serves as a standard for future comparison with the same or a similar cell, should doubt arise as to the effect of accidental rough usage.

All scale-readings begin at zero, and extend by practically uniform increments to the maximum reading. The range of scale-readings for instruments of a given maximum scale is thus greater than is common; and, as the divisions of each scale are the result of individual calibration and checking, the scale-readings are uniformly accurate. The temperature correction is negligible, and the instruments can be kept constantly in circuit, as their resistance is so high (averaging twenty thousand ohms) as to prevent any appreciable heating error. The ammeters have the same general appearance as the voltmeters, and possess the same merits of permanency and reliability.

In the hands of electricians and electrical engineers, these instruments are claimed to afford the means of obtaining measurements

We may fairly conclude, then, from all of these experiments, that the effects observed in the micrometer circuit were produced by oscillations in the discharge circuit of a period approximately equal to that calculated from the dimensions of the apparatus, in the neighborhood of a hundred-millionth of a second.

Hertz concluded, that, if vibrations were caused in the micrometer wire, there must be nodes (points of zero disturbance) somewhere

FIG. 5.

Curve showing relation between length of side of rectangle (taken as abscissa) and maximum sparking distance (taken as ordinate), the sides consisting of straight wires of varying lengths.

FIG. 3.

along its length. To prove this, he adjusted his micrometer circuit to resonance with the discharge circuit, making the gap in the former so wide that sparks were just able to pass. Then a sphere was made to touch different points along the wire, the result being a cessation of the sparks except when the point of contact was at the middle, showing that there was a node at that point. Again, by using a second micrometer circuit similar to the first, as in Fig. 5 (Fig. 7 in the paper), nodes were found to occur on *cd* and *gh*. When the wire connecting 2 and 4 was removed, the vibrations were not disturbed; but when the knobs at these points were brought close together, a slight spark was observed between them, the spark corresponding to a vibration with a single node at *ae*. We can, then, in the same conductor have vibrations with one or two nodes, according as we wish; that is, we can excite in it its fundamental

correct to within one-fifth of one per cent, and special instruments are made correct to within one-tenth of one per cent. If the limits of error were even ten times as great as claimed, these instruments would, it is said, possess greater accuracy than has been heretofore attainable in commercial voltmeters and ammeters. It is most certainly to be hoped that actual practice will substantiate the accuracy of these claims.

ELECTRICAL NEWS.

Hertz's Researches on Electric Oscillations.¹

IN order to get resonance phenomena between two circuits, Hertz used an arrangement consisting of a straight copper wire divided into two parts by a discharger, the two halves being connected with the secondary of an induction-coil, while two hollow zinc spheres were arranged to slide on the halves. The micrometer circuit was made of such dimensions as to have a slightly shorter period than that of the discharge circuit, supposing the oscillations were really as rapid as was calculated. The experiments were made in two ways. First, the period of the micrometer circuit was increased: the result was an increase in the length of the spark that could be obtained in it, followed by a decrease, as the capacity, and therefore the period, became too great. Afterwards, the micrometer circuit remaining constant, the period of the discharge circuit was decreased, the result being, as before, an increase in spark-length in the micrometer circuit, followed by a decrease.

¹ Continued from No. 313.

FIG. 6.

Curve showing relation between length of side of rectangle (taken as abscissa) and maximum sparking distance (taken as ordinate), the sides consisting of spirals gradually drawn out.

note or its first overtone. As to the higher overtones, Hertz considers it doubtful whether it is possible to produce them, for the results show that the damping effects must be considerable; and there are many secondary phenomena which show that irregular vibrations are superposed on the regular ones. To obtain the best results, Hertz observes that there is a longer spark in the secondary when it is exposed to the light of the discharge circuit.

Let us now call the discharge circuit the primary, and the micrometer circuit the secondary. The next experiment Hertz tried was with a primary circuit of straight copper wire, carrying at its ends zinc

spheres, and having a break in the middle for the discharge spark; the secondary being a circle of copper wire, broken by an air-space which was capable of adjustment by means of a micrometer screw. The two were adjusted until they were in unison, and the effect of the primary on the secondary was observed for different positions of the latter. There are in reality two electro-motive forces acting upon the secondary, — one an electro-static force, due to the rapid variation of the distribution of charge on the primary; the other an electro-magnetic effect, due to the current oscillating back and forth on the primary wire. Now, it is a matter of very great im-

FIG. 7.

portance to find the effects of these two. In the lower part of Fig. 6 (Fig. 8 in the paper) the lines *mm* represent different positions of the secondary, which was vertical. The sparks in the secondary disappeared when the air-space was in the horizontal plane passing through the primary, and were a maximum for points at right angles to these. The arrows give the resultant force, which does not differ greatly from the electro-static distribution due to charges on *A* and *A'*.

When the secondary was horizontal, as in the upper part of Fig. 6, in position *I* there were two maxima of spark distance, when the air-space was at a_1 and a'_1 ; in position *II* the maxima were at a_2 and a'_2 , the distance at a_2 being the greater; in position *III* there was but one maximum, at a_3 , with a point of disappearance at a_3 ; at *IV* there was a maximum at a_4 , a minimum at a'_4 ; at *V* there was a maximum at a_5 , a minimum at a'_5 . From the position *III*

FIG. 8.

to the position *V* the line *aa'* swung rapidly from a direction parallel to *AA'* to one perpendicular to it.

Now, what all these experiments mean is this: the electro-static force is more important than the electro-magnetic within the distances at which observations were made, excepting in the last cases, *IV* and *V*, where the electro-magnetic force comes in. But, as it is of the greatest importance to find out what takes place at a distance from the primary, Hertz extended his observations until the secondary was as much as 14 metres from the primary. At a distance of about 1.5 metres the maxima and minima became indistinct, but beyond this they were clearly defined again. From his observations, Hertz plotted out the distribution of force in the

room, the result being like Fig. 7 (Fig. 9 in the paper), where the lines indicate the direction of the force, the stars representing the points where the direction is indeterminate. We see that at distances beyond three metres the electro-motive force is everywhere parallel to the primary, — that is, the electro-static effect is negligible, — and we find that the effect diminishes very much more rapidly in the direction of the vibration than at right angles to it. For less distances than one metre, the distribution of electro-motive force is practically that of the electro-static force.

There are two lines at all points of which the direction of the electro-motive force is determinate, — the line in which the primary oscillation takes place, and a line at right angles to it. But there are regions in which the electro-motive force becomes indeterminate: these form two rings around the primary, the projections being the stars in the figure. Since the electro-motive force within them acts very nearly equally in every direction, it must assume different directions in succession, for of course it cannot act in different directions simultaneously. The observations, then, lead to the conclusion that within these regions the magnitude of the electro-motive force remains nearly constant, while its direction varies through all the points of the compass during each oscillation. Dr. Hertz thinks the results very difficult of explanation, unless we suppose the electro-static and electro-magnetic electro-motive forces are propagated with unequal velocities, in which case we have within the annular regions two electro-motive forces at right angles, and differing in phase; and as a consequence the resultant will turn through all the points of the compass at each oscillation.

One great value of the above series of experiments lies in the fact that they enable us to put aside such theories as do not agree with the observed results; and, as there are a considerable number of theories, we are thus saved much confusion.

The next subject which Hertz took up was the idea of displacement currents in a dielectric, — an idea which underlies so much of Maxwell's work. Briefly, the assumption made by Maxwell is, that, if two conductors are charged positively and negatively respectively, then in the dielectric between them there is a corresponding displacement of electricity across any surface surrounding either. The displacement current lasts as long as the conductors are being charged, and has magnetic effects, just as a current in a conductor has. To show the existence of these displacement currents, Hertz arranged the experiment shown in Fig. 8 (Fig. 10 in the paper). Here the primary circuit consisted of the two conductors *A A'*, joined by a wire with the air-space for the discharge in the middle. The secondary circuit was adjusted in unison with the primary, and was placed in such a position that there was no sparking. If, now, a conductor *C* be held near *AA'*, equilibrium was disturbed, and sparks passed at *f*. On removing *C*, and approaching a dielectric, if no effect was observed, then the dielectric would be shown to have no magnetic action, and Maxwell's theory would fall to the ground. But on trying the experiment, a decided effect was produced, thus proving that the dielectric exerted magnetic actions, and that Maxwell's notion of displacement currents is in all probability correct.

ELECTRIC PLANTS IN THE NAVY. — The report of the naval inspector of electric lighting, Lieut. R. B. Bradford, contains a summary of the work performed under the supervision of this office. After describing the installations on the "Trenton," the "Omaha," the "New Hampshire," the "Atlanta," the "Boston," the "Chicago," the "Yorktown," the "Baltimore," the "Charleston," and the "Pensacola," the report goes on to say that search-lights are at times very useful, but discretion must be exercised as to when and how to use them. During the recent English evolutionary squadron exercises, the search-lights of the blockading squadron failed to detect the escaping ships of the enemy, which had, of course, all lights out and every thing visible carefully colored a dead black. On the other hand, the enemy's ships which were not trying to escape used their search-lights to blind the eyes of the blockaders and interfere with the rays of their searchers. Recent experiments in Russia indicate that it is not an easy matter to disable a search-light with machine-guns and shoulder-rifles, on account of the light blinding the eyes and interfering with the aim. It is found in Germany, however, that if search-lights are placed

behind men with the beam of light on a target, very good practice can be made, so long as the men are in the beam, the sights of the guns then being illuminated; if, however, the men are out of the beam, and consequently invisible, the accuracy of the practice is much reduced.

THE AXO BATTERY.—The most widely used galvanic cell for "open-circuit" work—that is, for bells, burglar-alarms, telephones, etc., where the current is only taken out for short times—is the Leclanché, or some of its modifications. The cell has many advantages: it needs very little attention, its electro-motive force is comparatively high, there is no eating-away of the zinc when the cell is not working. The only troubles have been in the evaporation of the liquid, the creeping of the solution over the edges of the jar, and the corrosion of the

binding-post contact at the carbon pole. These defects are remedied in the new Axo type of Leclanché cell shown by the illustrations. Here the porous cup forms of itself the cover of the cell, which is hermetically sealed by pouring wax or paraffine in the space between the top of the cup and the edge of the jar. As the depolarization of the battery requires that there be a certain amount of ventilation, this is secured by deep grooves in the sides of the carbon, coming above the cover of the jar. It will be seen that the zinc passes through a separate hole in the side of the jar, which is closed by a rubber stopper. The connection with the carbon is made by a patented metallic clamp and thumb-screw, shown in the figure. Taken altogether, the Axo is an advance in galvanic cells. It can be sealed and left to itself, until, as must finally happen in every battery, the zinc and solution have to be replaced, when with very little trouble it can be practically renewed. For ordinary bell-work it would probably last a year or more without attention.

NOTES AND NEWS.

PROFESSOR SHALER of Harvard has returned from his tour of geological exploration through the Dismal Swamp.

—The Rev. Dr. George E. Reed, pastor of the Trinity Methodist Church of New Haven, is now at work upon his letter of acceptance as president of Dickinson College of Carlisle, Penn.

—Mr. F. Küstner has made a very interesting series of observations on the aberration of fixed stars, and, from certain discrepancies between early observations made by Struve and recent ones made by himself, arrives at the conclusion that the altitude of the pole, which is assumed to be a constant in the formula applied, is in fact variable. He found that in the fall of 1884, at Berlin, the polar altitude must have been 0.2" greater than before and after that season. As this result appeared somewhat startling, he subjected other observations made at Pulkowa and Gotha to a thorough investigation, which proved the correctness of his view. Mr. Küstner

attributes these variations to meteorological and hydrological phenomena which are caused by the action of the sun. Helmer's investigations tended to show that these irregular movements of matter might result in changes of latitude not exceeding a few hundredths of a second, while William Thomson concluded that these changes might be as great as half a second. From Küstner's observations, it appears that the real changes are intermediate between these two values.

—Professor Hill of the School of Geology of the University of Texas plans the establishment at the university of an educational museum which will represent in the broadest sense the geologic conditions—structural, economic, organic, and general—of the earth, and to illustrate these features as far as possible by Texas material accompanied by maps, models, and labels. This museum will exhibit not merely the extraordinary, but also the far more important and too little valued ordinary features of that State; so that any person, citizen or stranger, will find compactly arranged in the halls of the university a complete and instructive synoptical exhibit of all the diverse natural features of Texas. The museum will also be a medium of exchange with similar institutions outside the State. The attention which will be attracted abroad by properly prepared and representative specimens from Texas, conveying clear and accurate scientific information that can be disseminated in no other manner, will attract the earnest interest of a class of intelligent people who cannot be otherwise reached. The functions of the museum will also be distributive as well as collective, and its utility not confined to the university building, but disseminated throughout the State, it being the intention to select from its duplicates typical educational series for distribution to high schools connected with the university wherein the natural sciences are taught.

—A movement has been started in Norway, says *Nature*, for the despatch in the summer of 1890 of an expedition which will try to reach the north pole, and it is proposed that the leadership shall be offered to Dr. Nansen. Those who are arranging the plans maintain that no other country could furnish such a crew of experienced and hardy ice-men and arctic travellers as Norway, and that a winter or two in the arctic regions would affect these men very little. The intention is that an attempt shall be made to reach the pole by way of Franz Josef's Land, a route advocated by the most experienced Norwegian arctic travellers as well as by several well-known men of science who have studied the problem. *Szö*, which have played such a prominent part in the Norden-skiöld and Nansen Greenland expeditions, would no doubt again be of great service.

—The board of overseers of Harvard College, at a meeting held Jan 30, adopted, after prolonged discussion, the following vote: "Voted, that, in the opinion of this board, it is expedient that every undergraduate be requested to report in person early every morning, with a moderate and fixed allowance for occasional absences; that attendance at the exercises of each course be more rigidly enforced; that the system of advisers, somewhat as applied to special students, be extended to the freshman class; that the reports of the presence and absence of students be collected daily by monitors, and daily entered on the books; that no choice of studies made by a student be valid if it calls for more than three lectures or recitations on any day of the week, unless the choice has been specially allowed by the dean; that, in order to make it more difficult for students to prepare by a brief period of cramming to meet the tests applied, the faculty require all the instructors to provide tests of the progress of their students with sufficient frequency to enable them to enforce effectively Section 7 of the Regulations; that admonition be administered by the dean on his sole authority, and that the powers of that officer be so enlarged, at whatever increased expense it may be necessary to incur, that the records of attendance may always be ready for inspection by the proper officers; that the faculty be asked to prepare and report a series of rules, which, in their judgment, will give practical effect to these recommendations." This was adopted by a vote of 16 yeas to 4 nays, those voting in the negative being President Eliot, Dr. Phillips Brooks, Dr. Walcot, and Charles R. Codman. The carrying-out of these recommendations will depend on the faculty, which, it is understood, are opposed to their spirit.

THE MANY KIND and appreciative words that our recent editorial comments on school matters have called forth are sufficient proof that we have succeeded in arousing an interest in this most important matter. Our Wednesday of last week the New York City Board of Education discussed the report of the committee on reform, but adjourned without taking any action. As we go to press, the matter is again under discussion. The character of the meeting of last week is now re-assuring. The "wrigsters" in the board received Mr. Webb's opening remarks in sullen silence, and, when finally one commissioner did find his tongue, it was to say that no marking system prevailed in New York city schools! This astounding statement is so transparently false, that we are quite at a loss to know why it was made. We can only interpret it as a sign that the opposition propose to treat the whole matter with an ignorant bravado. This attitude, however, will not be tolerated by the public nor by the independent section of the press. The question must be squarely met, and a vote must be taken. Another commissioner, one who knows nothing whatever about the schools as they now exist, proclaimed that they were perfect, and cited himself, a graduate of them, in evidence. This line of argument

will hardly be accepted as conclusive. The well-known fact is, that abuses of the most outrageous kind exist,—favoritism, political methods, bad teaching, and the rest,—and they are wasting the lives of hundreds of thousands of children. The Board of Education *must* cope with them.

THE AMERICAN [AUTHORS'] COPYRIGHT LEAGUE has issued an appeal, asking the support, by all interested, of the Chace-Breckinridge Copyright Bill, which passed the Senate May 10 by 34 to 10, and is now before the House of Representatives. This is a compromise measure, the outcome of years of labor. Whatever its defects, this bill, the league believes, "will put a stop to the habit of piracy; will free American authors from the competition with stolen goods; will enable American writers to support themselves by their pens; will make American books cheaper by opening to them the broad home market now supplied with inferior foreign work; will give American books a chance to reach the American people, who now read many worthless books by foreign authors, reprinted in rival editions solely because they can be had for nothing; will result in securing to American authors important and growing foreign markets; and will take from our country the stigma of being the only great nation in the world which despoils the foreign author."

In this connection it is interesting to note, that, according to the Washington correspondent of the *New York Evening Post*, "the friends of the Copyright Bill have a plan for bringing up the bill in the House which they hope will be successful. The plan is to have a rule reported that will cover this bill. The great difficulty has been to induce the Republicans to agree not to insist that any such rule shall be amended so as to make it in order to call up pension-bills for passage. The Democratic Representatives are determined to resist any further pension legislation in this Congress. Some of the Republicans think that they have made all the 'record' as to pensions that is necessary, and that it is expedient to pass the Copyright Bill. There was a dinner on Saturday night, Jan. 19, which was attended by Mr. Houghton of Boston, Edward Eggleston, and others interested in the copyright matter, and by some of the leading members of the House, including Messrs. Cannon of Illinois, Long of Massachusetts, Adams of Illinois. Some of the Western members have been influenced by the concentrated attack upon the bill that has been made by the American Press Association, which furnishes the country newspapers with patent insides. The friends of the bill are endeavoring to counteract this influence, and to answer the stereotyped petitions which have been sent to the country newspapers for signature. Dr. Eggleston reports that a large majority of members of Congress, who at the opening of the session found their mails crowded with bogus petitions purporting to come from typographers, have had their eyes opened to the fictitious nature of these petitions by the representatives of the typographical unions who have visited Washington to assure members that the unions are heartily in favor of the bill, and that the opposition is, so far as they can find out, supported and paid for by certain British publishers who are afraid to lose business if the bill becomes a law. The fact that the *Union Printer* of New York, edited by W. M. Rood, and which is the official organ of the typographical unions in that part of the country, is giving hearty support to the bill by editorial articles, and joining hands with the organ of Union No. 2 of Philadelphia, shows the spirit in which the members of the craft are taking hold of the matter."

THE ANNUAL REPORT of the president of Harvard College is always looked for with interest, and for some years past *Science* has made it a custom to call attention to this report as soon as it is issued. The report of 1887-88 is before us; and, while it contains no features of striking interest, yet it chronicles a steady progress

along the line which the authorities of Harvard have marked out for themselves. Appreciative reference is made to the work of Professors Asa Gray and Ernest Young, who died during the year, and also to Robert D. Smith and James Freeman Clarke, whom death removed from the board of overseers. Mr. Eliot notes the fact that in 1888 the examinations for admission to the college were for the first time conducted exclusively on the new plan announced in 1886. It seems that the secondary schools and the private tutors have already responded in considerable measure to the new suggestions and requirements of the faculty. Of the 315 candidates who completed their entrance examination in 1888, 31 presented the history of the United States and of England instead of the history of Greece and Rome; and 93 presented elementary experimental physics, as recommended by the faculty, instead of descriptive physics and astronomy. Both French and German were presented by 110 candidates. The figures prove that the new requirements have already stimulated the teaching of modern languages in secondary schools, and have promoted the introduction of laboratory methods of studying physics and chemistry. It is pointed out that in the progress of converting Harvard College into a university of liberal arts and sciences, about the same gain was made in 1887-88 as in each of the years immediately preceding. "Progress," says President Eliot, "may be made in one or more of four principal directions: (1) in amplitude of instruction; (2) in freedom in choice of studies; (3) in better arrangement and co-ordination of studies within single departments; and (4) in *morale*." The gain in the volume of instruction during the year 1887-88 was about five per cent; that is, from 485 hours a week to 510 hours. In respect to freedom in choice of studies, the freshmen gained access to several departments from which they had previously been excluded; namely, Spanish, Italian, and music. President Eliot holds that it is to the advantage of every department that its elementary studies be open to freshmen, because otherwise the advanced courses of the department might not be reached in due season. In respect to co-ordination of courses, there was an entire recasting of the whole set of courses in physics, with the result of securing a better sequence of subjects and a more complete covering of the ground. Additional facilities were afforded for taking up advanced study and research in German and in Romance philology.

The *morale* of the college has been favorably affected by several causes. The voluntary method in the religious services gives satisfaction to teachers and students. "It meant the permanent removal of the question of conscience, and the drying-up of a constant source of irritation and ill feeling, and the reparation of what many believed to be a grave injury to religion, and the establishment at the heart of the university of a fresh, strong influence for good." Under a new regulation, also, the instructors have the power to exclude from their courses any students who neglect the work required of them. This power has been extensively used, and as a result the discipline and the progress of the students have improved. The question of athletics has been settled to the satisfaction of every member of the university; and Mr. Eliot adds of the faculty, "that they hold that dyspepsia is less tolerable than a stiffened knee or thumb, and that effeminacy and luxury are even worse evils than brutality." We notice, also, an interesting remark in this report regarding the physical condition of students holding scholarships. It seems that the college is now paying out more than fifty thousand dollars a year to students who need aid to complete their education. Heretofore it has been usual to pay no attention to the bodily condition of the recipients of this beneficiary aid, and it is believed that these recipients fall below the average of the whole body of students in health and vitality. It is now provided that holders of scholarships shall present themselves twice in the year to the director of the gymnasium to be examined as to their physical condition, and to receive suggestions as to the care of their health. The summer courses, the library, and the professional schools are all touched upon, and valuable information is contained in the appendices.

SCIENCE AND THE DICTIONARY.

ONE of the most important accompaniments of the progress of science, indeed an essential factor in it, is the increase of its vocabulary. Every advance in accurate observation, discovery, analysis, or constructive theory, brings with it a new term, or, more often, a group of terms. This multiplication of words is largely inevitable. The new things must, of course, generally receive new names, and the new ideas will not always fit into the frames of association in which the old words are set. The scientific demand for precision and brevity must be satisfied even if linguistic purity suffers. It thus happens that every year the language of science receives a large addition which students of science must understand and use. How very large this increment is, it is difficult, even for those who are familiar with several departments of science, to appreciate. Moreover, the process of growth does not stop with what is necessary. Unfortunately, the liberty which in many cases must be taken with the language has led many reputable scientific men to feel that they are free to do what they please with it, in any case. The result is a vast number of coinages which might have been dispensed with, but which must be learned and remembered, since they often become current through the reputation of their inventors. The number of such words increases at the rate of probably several thousand a year.

To this increment through direct coinage must also be added the numerous, and not less significant, specializations and enlargements of the meaning of established and even common words, such as "energy" and "potential." Every movement in science unsettles much that has been done before, and of this continuous re-adjustment its language is a true reflection.

It is obvious that at this point science can receive a great deal of help from competent lexicographic aid. While the dictionary is not, in many respects, an adequate exponent of scientific knowledge, it may be an invaluable record of the greater number of the elements or details of that knowledge. Its aim is, of course, necessarily to state merely what is or has been in the language it describes, not what scientifically ought to have been; but, if it is accurately and intelligently performed, this historical labor approaches in its value to science very near to original work. It is true, also, that the utility of the ordinary dictionary is limited by the narrowness of its definitions and the formalism which marks its treatment of its material; but these defects are largely conventional, and it is quite possible for an editor who understands the wants to be met, and who has the necessary disregard of traditions, to model a dictionary which will satisfy every reasonable scientific demand. In a word, the impossibility now felt of keeping track of the linguistic development not only of science as a whole, but even of one specialty, and the difficulty of guarding even established words from misuse or abuse, make the construction of a dictionary which will not only record the entire vocabulary of the sciences, but will record it and define it so fully and accurately as to conform to the needs of scientific men, one of the most urgent requirements of the time. It is therefore worthy of note that the attempt has been made in this country, and by American scientists, to produce a book of this kind. It is announced that the "Century Dictionary," which has been for some years preparing, under the editorship of Professor W. D. Whitney, is to be not merely a complete general and historical dictionary of common English, but also an equally complete dictionary of technical terms; and that this technical material, which has been obtained by searching all branches of scientific literature, has been put into shape by competent specialists, who have had in mind the necessities of their fellow-craftsmen, as well as the wants of laymen. It appears, thus, that an effort is seriously making to embody for the first time comprehensively, in lexicographic form, the scientific spirit and work of the nineteenth century; and while it is to be expected that the most direct result of the attempt will be the promoting of popular intelligence, it is also to be expected — from the reputation of the distinguished editor-in-chief and of his co-laborers, among whom are Professor J. D. Whitney, Professor E. S. Dana, Dr. Sereno Watson, Dr. Lester F. Ward, Professor C. S. Peirce, Professor T. C. Mendenhall, Professor R. H. Thurston, Dr. Elliott Coues, Professor Theodore Gill, and many others — that the interests of pure science will not be neglected.

SPEECH AND ALPHABETICS.¹

I HAVE never practised offhand utterance on any subject. I have always had to write what I had to say; so that I have enslaved myself to a method which I cannot now hope to change. The method, however, has this advantage; namely, that it keeps one to the point, prevents rambling of thought and vagueness of expression, and so enables one to be exact to his intention, both in outline and detail. I do not mean that an address on such an occasion as the present should be read, but that, however little used, the presence of paper secures presence of mind. On the whole, therefore, I do not know that I should greatly care to change my method, even if I could.

We are called on to say something on the subject that most interests our thoughts. This requirement will, of course, furnish excuse for whatever of egotism there may seem to be in our response to the call. For my part, I can say, that, while I have from time to time ridden an occasional hobby, there has always been one subject of abiding interest which has persisted in maintaining prominence in my thoughts from my earliest days until now. That subject has been "Speech and Alphabetics."

I had hereditary leanings to the profession of teacher of vocal physiology, which no doubt influenced the current even of my boyish thoughts; and when, in 1841, I began to prepare myself for independent work, I sought to supplement what I may call the family knowledge which I possessed, by the study of all available books on the subject. I found, however, that but little assistance was to be obtained from this source; for the art of treating defects of speech had been shrouded in secrecy by nearly all its practitioners. My father was, in fact, the first to repudiate occult methods in the cure of stammering; and to practise his system openly. At the time I speak of, there did not exist in print, so far as I could discover, any precise directory for the processes of articulation. I aimed at teaching these processes, but could not find a single work that gave specific guidance as to what to do, or how to do it, in any given case. Under these circumstances, I had to investigate from my own organs and the organs of my pupils. I had many pupils, exhibiting wide varieties of defects and peculiarities, and the observations on these by day became the study of the night. I may add, however, that my night-work never interfered with day-work; that it invariably terminated not later than two in the morning, while the day-work invariably began not later than ten. This was very nearly the philosopher's division of the twenty-four hours, — one third for work, one third for recreation, and one third for rest. But my work and recreation were inseparable. Work was one half recreation, and recreation one half work, on the principle that "the labor we delight in physics pain," or, in other words, is recreative.

Years of this pleasurable devotion to one subject ultimately developed what I had sought in vain to find as a legacy from professional predecessors. In 1849 the first results of my labors were published under the title of "A New Elucidation of the Principles of Speech and Elocution," forming the kind of directory which I had desiderated before I began to teach. But this work was far from exhausting my phonetic material, which was still, moreover, increasing. I had become experimentally acquainted with a category of sounds far exceeding those in any language. The peculiar elements in Gaelic, Welsh, Scotch and Irish dialects, provincial and metropolitan English, American English, French, German, etc., — as well as those accidental sounds produced by stammerers, lispers, persons with cleft palate, deaf-mutes, etc., — were familiar to my ear and my vocal organs; and I sought long to incorporate them into one phonetic scheme, where each sound should find its place in due relation to every other sound. The process was the converse of that which had been tried for the collation of a universal alphabet. Eminent linguists had endeavored to collect from all known languages the sounds of each, and from these to frame an alphabet by which all tongues might be uniformly written. But no success had attended the efforts, because the identities and differences among the elements could not be satisfactorily determined. At a conference held in 1854, the object thus aimed at was finally abandoned, and declared to be impossible.

¹ Address by Professor A. Melville Bell, delivered in Washington, D.C., Jan. 28, 1889.

A different basis, however, seemed to me to promise a different result. My aim was to find a physiological instead of a linguistic basis for the desired universal alphabet. I therefore sketched out mouth-regions, divided as it were by lines of latitude and longitude, and endeavored to locate in my chart every sound which I could form or which I could distinguish, whether linguistic or not, so as to bring under review all the varieties that could be produced by the organs of speech. From such a category, I reasoned, the phonetic elements of any and every language might undoubtedly be selected and identified. The undertaking was an arduous one, filling up the night-work hours of many years; but it was at last accomplished, in the system of "Visible Speech" published in 1867.

Naturally, you will perceive, some aspect of my life-topic must still be one of the principal subjects of my thoughts. "Visible Speech" furnishes, in a universal alphabet, the necessary vehicle of a universal language, whenever, if ever, such a bond of human brotherhood shall become an accomplished fact. In the mean time, the system, as an educational implement, performs services both novel and valuable: so I might leave it now out of my thoughts. But I have recently been invited, from an influential quarter, to prepare a popular manual on the subject; and, in working at this, I have developed some new points, which will, I think, add greatly to the scientific value of the system.

The phonetics of our own language have lately claimed my chief attention. Our words have settled into forms irregular, incongruous, and bristling with difficulties to the learner. Every lover of the English tongue must wish that some means should be adopted to render it more easy of acquirement. To us who have mastered the difficulties, each word has, by association, become a thought-picture, of which every letter is a necessary part; and we look upon any disturbance of the orthography to which we are accustomed as we would upon distortion in a drawing. What is called "spelling-reform" is therefore, to perhaps nine persons out of ten, an abomination. If no other means were possible to lessen the labor of learning to read, the objectors to spelling-reform would no doubt yield to the inevitable, and lay aside prejudices and predilections from philanthropic motives; but they cannot be asked to do so while any method remains for obviating the tyro's difficulties without offending the educated, by changing the aspect of our literature.

Thinking on this subject, the idea occurred to let spelling alone, and make a perfectly phonetic version of our common alphabet by limiting each letter to its one most usual sound, discarding unnecessary letters, and designing new letters for unrepresented sounds, so as to form a separate initiatory system for children and foreigners. One primary object was to preserve such a resemblance to ordinary letters as might enable any person to read the new as readily as he does the old. By means of the amended alphabet, the time of learning to read may be reduced to a fraction of that required with common letters, while the exact sound of every word is deduced from the writing of the word itself.

There can be no doubt that a child, or a foreigner, who has learned to read from phonetic letters, will, with little or no further instruction, read also from common letters; and he will learn spelling by the mere contrast with phonetic writing. Spelling is thus always learned pictorially, by the eye, and not mentally, by rule.

One other point. English grammar, as compared with other grammars, is so simple that any alteration in it can scarcely be considered necessary; nevertheless the few existing irregularities may be removed from initiatory books without affecting standard English. I have pointed out elsewhere how this may be done.

English is already the most widely used of all tongues; and the adoption of the amended alphabet will facilitate its diffusion, so that it may speedily become the general medium of international communication throughout the world, — in briefer phrase, world-English.

Interest is hard to be aroused, except when some selfish object is to be attained. We have no personal benefits to be derived from the system which I advocate; but coming generations have, and so has all the outer world. Indifference is not a proper mental attitude in reference to such a subject. National pride, if no higher motive, should urge to effort, and liberality in furtherance of effort,

to render more perfect and more easily accessible, at home and abroad, our noble language and our glorious literature.

Now, I have not only told you the subject that most interests me, but explained the origin of my interest in it, and endeavored to excite your interest in it also. Pardon so much use of the first person. The narrative could not be cast in another mould.

SOMETHING ABOUT TORNADES.¹

WHAT are the local signs of conditions favorable to the formation of tornadoes? 1. The prevalence of southerly winds, with a gradual but continued increase of heat and moisture; 2. A sultry and extremely oppressive condition of the atmosphere, which is sometimes characterized as "sticky," or so quiet as to call forth the remark that "there is not a breath of air stirring;" 3. The form, motion, character of development, and place of formation, of clouds. The sudden appearance of ominous clouds, first in the south-west, and then almost immediately in the north-west and north, is sufficient to attract the attention of the most casual observer. In nearly all instances, these premonitory clouds are unlike the ordinary formation which signifies rain, and perhaps a thunder-storm. If the clouds are light, they resemble smoke rising from a burning building; if dark, they present a deep greenish hue, which appears to increase in intensity as the storm advances. Sometimes these dark clouds appear as densely black masses of smoke, rolling upward from the chimney of an engine. The motions of the clouds are peculiar, in that they appear to be rushing from every quarter towards a common centre, making the incipient stages of a gyrotory motion in the cloud region. The next step in the progress of development is the appearance of a small darting tongue of cloud, which suddenly proceeds downward from the centre of commotion, and ultimately reaches the earth as the full-fledged funnel-shaped tornado-cloud.

This brings us to consider what are the signs of its approach. The tornado-cloud is, of course, not visible from all directions while sweeping the earth. The limit of vision is necessarily greater in some cases than in others, depending upon the topography of the intervening country. Where the funnel-cloud cannot be seen, its existence can readily be distinguished by the peculiar roaring noise which is likened to the rumbling of distant thunder, or the approach of a heavy train of cars. The noise is said to resemble the "sighing of the wind through the forest." As the storm approaches nearer, the sound increases in intensity until the final crash of the elements, which comes with the suddenness of an explosion. The noise is sufficiently peculiar and distinct to create an alarm, and, as a means of warning, must not be ignored. A few moments before the assault there is a death-like stillness in the air. The observer's eye catches the absence of any movement in the leaves upon the trees, which a moment before danced in a gentle wind. The ominous silence portends grave results, and requires that no time be lost in seeking the most perfect means of safety.

The form of the tornado-cloud in individual cases is somewhat variable; but it always tapers from the top downward, the smaller end being nearest the earth. It is described by eye-witnesses as resembling an "elephant's trunk," "balloon-shaped," "egg-shaped," "basket-shaped," etc. While passing along its path, the cloud is characterized by four distinct motions, which may be designated as (1) the "progressive motion," generally from some point in the south-west quadrant to some point in the north-east quadrant; (2) the "whirling or gyrotory motion," always from right to left, or contrary to the movements of the hands of a watch with the face upward; (3) the "curvilinear motion," where frequently the cloud rises from the earth, breaking the continuity of its path for a distance of several rods to as many miles, then returns suddenly to the earth with renewed energy, continuing its violence as before; and (4) the "oscillatory motion," a swaying from side to side of the central line of cloud movement. (This motion is sometimes quite sudden, but generally it is a moderately slow motion, and easily identified: the regularity of it depends upon the frequency and severity of the indraughts of air from the south side of the storm's path into the vortex of the cloud).

¹ Portion of a paper read before the National Geographic Society of Washington, Nov. 16, 1888, by J. P. Finley, continued from *Science*, No. 313.

It is important here to state that the south or right-hand side of the tornado is the most dangerous part of the storm, as it is also in the case of the cyclone. On this side the inflow of air toward the vortex coincides both with the progressive motion of the tornado and with the general easterly movement of the "low," thereby increasing the velocity of the southerly currents. On the north or left-hand side of the tornado the incurving winds oppose the direction of the currents advancing to the vortex, and therefore the force of the wind is very much less on this side: it is therefore the safest side of the storm. The tornado-cloud is swept along by the general currents prevailing in the south-east quadrant of the "low," and whatever may suddenly affect these movements will also extend its influence to the tornado-cloud, and thus increase or diminish its gyrations, sometimes to the extent of withdrawing the cloud entirely from the earth. The tornado continues in the full manifestation of its power until the force arising from the gyrations is no longer adequate to keep the pressure and temperature in the vortex low enough to cause condensation; and therefore the lower part of the cloud vanishes first, the decrease of power continuing until nothing appears on the funnel, and a dark, irregular mass of cloud marks the spot from which the spout had previously depended.

"Windfalls" are the tracks of tornadoes through forests, as shown by the prostrated and confused masses of timber. In many cases there remain but the skeletons of these ruins, and their location is known only to Indians, trappers, hunters, and surveyors. There is not a State east of the Rocky Mountains that has escaped these serrated tracks through its forests, and the record of their occurrence will in many cases be found upon the plats of the early State surveys. Windfalls both of recent and of very early date are still to be found in the forests east of the Mississippi. The late Professor I. A. Lapham of Milwaukee, Wis., attached to the signal corps in 1870-72, made, in the latter year, a very exhaustive and interesting report on the windfalls of Wisconsin. As the result of a very careful examination of the plats of public surveys made within the State, he discovered and marked upon a chart the location and approximate length of path of three hundred and sixty windfalls or tornadoes.

The successful protection of life depends upon the position and surroundings of the observer on the approach of the tornado, the character of motion possessed by the tornado-cloud at the time, the width of the path of the storm, and the velocity with which it is moving.

The following precautions have been determined upon as the result of careful investigation, observation, and experience: 1. The south side is the dangerous portion of the tornado, the north side is the safe portion. 2. In the open country, never undertake to escape from a tornado-cloud without first making sure of the points of the compass, and that the direction which you propose to take is in a line at right angles to the path of the advancing cloud. 3. If the cloud is moving to the north-east, then the line of escape is to the north-west; if to the east, then to the north. Stand facing the advancing cloud in the direct line of its approach, and the safe side is always to the right. 4. To make escape certain, the tornado-cloud should be about three-fourths of a mile distant. This gives the observer a momentary chance to ascertain the character of motion it possesses, the velocity of progression, the width of the path, and the points of the compass. These estimates must of necessity be approximate, but can be made sufficiently accurate to be depended upon. At a greater distance than three-fourths of a mile, it would be difficult, in most cases, for the observer to obtain this information with any degree of satisfaction, unless the atmosphere was clear, and the cloud advancing over the open prairie.

A frame building is safer than one built of brick or stone. The former is more elastic, and holds together longer. The latter goes down in the first crash, and the *débris* is whirled into a heap in the centre of the foundation. This is especially the case where a brick or stone building stands alone. In a block of such buildings, one structure supports another, and there is not quite so much danger of entire destruction. In any event, however, the brick or stone building is the most dangerous, because it so readily crumbles and separates into falling masses, that the inmates are never safe from injury.

In a frame structure the safest place is in the cellar, but in a brick or stone structure it is the most dangerous. In the former case, if the building is destroyed, it is invariably carried away from the foundation. In the latter case the cellar is filled with *débris*.

The safest building to construct is one made entirely of wood, with a "barn frame," and not exceeding one story and a half in height. Where several buildings are connected together in a row, the height may be increased one or more stories with safety. No structure that rises above the earth, however made, can resist the violence of the tornado, and therefore no building is safe as property, or as a resort to protect life. Under all circumstances, whether in a building or in a cellar, refrain from taking a position in a north-east room, in a north-east corner, in an east room, or against an east wall.

The tornado-cave offers absolute security to life and limb, and nothing can replace it for that purpose. This retreat may be constructed as a cellar-cave or as a "dug-out." In the former case an excavation is made in the west wall of the cellar, on a level with the floor of it, and carried under ground until a sufficient distance is reached to provide comfortable quarters for those who propose to occupy the cave. The overhanging roof must be supported by heavy timbers, and then arched over with masonry of brick or stone. This extra precaution concerning the roof is necessary to provide against any serious damage to it by falling timbers or heavy masses of *débris*. The excavation is made into the west wall, because the storm, always approaching from the west, will carry the *débris* away from that side. But even this favorable position does not preclude the probability of *débris* being thrown upon the cave by the whirling currents of the vortex. The extra care bestowed upon the roof is money and time well spent. Careful attention should be given to ventilation and drainage, and to making the retreat in every way as convenient and comfortable as possible. The extent to which this suggestion can be complied with will depend upon the pecuniary ability of the person concerned.

The "dug-out" is a tornado-cave, not necessarily connected with any building. The results to be secured are the same as those derived from the use of the "cellar-cave." The cost of a properly constructed tornado-cave, including material and labor, will range according to the quality, character, and strength of the material with which it is built, together with the price of labor, from a hundred and fifty to three hundred and fifty dollars. Such a cave will comfortably accommodate ten persons.

The rush of air into the tornado's vortex, and therefore the violence of the wind, depends upon the difference of barometric pressure between the inside and the outside of the storm. This difference has been observed to be nearly three inches, and may be very much more, for observations have never been made in the centre of the vortex. A gradient of three inches, however, will give a velocity of 323 miles per hour, which will exert a pressure of about 260 pounds per square foot against a surface exposed at right angles to the direction of the wind.

The explosive force of confined air in a tornado is enormously great; and frequently it is to this energy, rather than to the direct force of the wind, that the destruction of buildings is due. As a tornado-cloud passes over a building, if the air within is confined by closed doors and windows, and cannot readily escape, the explosive force, due to a very great difference in tension between the air inside and outside of the building, bursts asunder the walls, and throws the roof upward to a considerable distance. Eye-witnesses state that under such circumstances roofs have been uplifted a distance of five hundred feet. Cellar-doors have been blown away from their fastenings in the face of a strong wind coming directly against them, and corks have been blown out of empty bottles by the sudden expansion of the air within them. Many almost incredible instances of extraordinary violence by the explosive force of tornadoes could be given, but want of space forbids more than this general reference to such manifestations of the tornado's power.

There is no fact or record to show that an electrical discharge, or any manifestation of atmospheric electricity, ever directly and entirely destroyed a large stone or frame building; ever lifted a locomotive from its track; ever carried an iron bridge from its foundation, and twisted the framework into a shapeless mass; ever

rolled a boulder from its bed in the ground; ever embedded one piece of timber into another, after having carried the former several hundred yards in the air; ever carried bedding and clothing in the air for miles; ever elevated to considerable heights in the air, columns of water from ponds, lakes, and rivers; ever lifted animals from the earth and carried them over buildings; ever drew the water from a cistern; ever twisted a tree from its stump; ever turned a building upside down, or end for end, without otherwise injuring it.

Any method of reasoning which assigns tornado-development to planetary influence is, equally with the electrical theory of their origin, without foundation. We have but to realize that in the formation of the tornado, and other local storms of a similar character, the entire action of all the forces involved, even in the energy of the sun's heat, is embraced in that portion of the atmosphere within from two to three miles of the earth's surface.

Any influence emanating from the movements, conjunctions, or other periodical mutations of the heavenly bodies, distant hundreds of thousands and millions of miles, can only reach an infinitesimal amount, and is entirely inappreciable in its effects upon the atmosphere to produce local or general disturbances, especially near the earth.

It has been asserted that the conditions which give rise to the formation of the tornado-cloud result from the effect upon the atmosphere of the mere revolution of the planets in their orbits; that the circular movements in the atmosphere are propagated and continued by such influences. The effect is likened to that which would result from the whirling in different directions, in a large vessel of water, of several globes attached to the same spindle. Upon withdrawing the globes, after a number of revolutions, the surface of the water will be found covered with a network of eddies. The inherent fault of this simile is the fact, that, while the illustration provides for the circular movement of the bodies within the medium which is set in motion to give the characteristic whirls or eddies, the subject of illustration, the planets, perform their revolutions, not in the atmosphere (the medium to be set in motion), but millions of miles away from it, in another medium, concerning which little is known. The failure properly to apply the method of reasoning by analogy often leads the novice into making the most ridiculous assumptions. It would be more reasonable to assume that the revolution of the planets gave rise to the great disturbances of the atmosphere, embracing extended regions of country, which are known on the weather-map as "highs" and "lows;" but even here the same difficulties operate, although not so extravagantly as in the case of the tornado, with the narrow path of a hundred yards or more.

To forecast successfully the time and place of any atmospheric phenomenon is a difficult matter, largely in proportion to the area of country brought under the influence of the particular disturbance. There are, of course, other elements which enter into the calculation to render the problem, except under the most favorable circumstances, an extremely complicated one, where the accuracy of results is demanded. It is well known that the tornado has the most circumscribed area of all storms, while its violence has no equal in the entire range of meteorological phenomena.

A large amount of field-work, and instrumental and general observations extending over many years, relating to the conditions of formation of this peculiar class of storms in every part of the country where they were found to occur, was necessary as a foundation upon which to base investigations as to the origin, mode of development, and means of prognostication. I began this work, in addition to other duties, in 1879, under directions of the chief signal officer. The first field-work was done in that year, the second in 1882, and the third in 1885. Various reports were prepared and published concerning the development of particular storms, the origin and general characteristics of tornadoes, and the relation of tornado regions to areas of low pressure.

It was found that tornadoes generally occurred at a certain time of day; generally moved in a certain direction; were generally preceded by certain conditions of wind direction and velocity, and by a certain gradient of temperature; generally occurred in connection with a well-defined area of low pressure, and with a "low" of certain form and trend; and generally occurred in a certain

quadrant (south-east) of the low-pressure area, at a certain distance from the centre of the "low" as marked on the weather-map, in certain regions of the country and in certain months of the year, and in groups having parallel paths of progression and at distances between of but a few miles.

Official tornado-predictions began at the Signal Office, experimentally, on the 10th of March, 1884, and were made twice daily at 7 A.M. and 3 P.M., Washington time. The predictions were for certain districts, that portion of the United States embraced between the 77th and 102d meridians being divided into eighteen sections, with arbitrary boundaries. These prognostications terminated on Sept. 20, 1885; and during the season embraced by the work, all of the well-defined and most destructive tornadoes were predicted for the districts within which they occurred, from five to eight hours in advance of the reported time of their appearance.

After May 10, 1886 (the following year), the official predictions were announced to the public in accordance with the following order of the chief signal officer: "The indications officer will give special attention to conditions favorable to the development of severe local storms and tornadoes. When the reports justify the prediction of these storms, they will form a part of the general indications, the prediction to be that conditions are favorable for the occurrence of severe local storms or tornadoes, giving the names of the States where such storms are expected to occur."

It will be observed, that, upon deciding to make tornado-predictions part of the general indications issued daily to the public, the character of the districts was changed from those determined by arbitrary divisions, to those designated by State lines; in other words, the States themselves. Commencing July 1, 1886, a special chart (No. 5, Dew-Point and Local Storm Chart) was made up daily in the indications room of the Signal Office to furnish information from which tornado-predictions could be made. This chart was discontinued on July 1, 1888, and replaced by the general weather-chart from which the regular indications are made. Since Sept. 20, 1885, no official verifications of local storm-predictions have been made, but the results observed from the combined indications are in a measure satisfactory.

Personally, I am of the opinion that the forecasting of conditions favorable to the development of tornadoes, and designating the quadrant of a State in which such conditions shall give rise to local signs that the inhabitants of that section can rely upon, are entirely practicable. By this admission I do not mean to convey the idea that the exact path of the funnel-shaped cloud can be indicated in the despatch, for that would be impossible except by chance. The average width of the tornado-track is only a few hundred yards; and several of these storms may occur in the same county, with entirely independent paths of destruction, and distinct cloud-formations.

It doubtless appears that the quadrant of a State, especially the larger ones, is a very extensive area to cover with a single tornado-prediction; but the fact must not be overlooked, that, where the conditions are favorable for tornadoes, storms having various degrees of tornado violence occur here and there over a very large section of country. Therefore the scheme of local storm-predictions for State quadrants would seem to possess the elements of success; for, while the peculiar funnel-shaped cloud might not appear, the conditions would be such that local storms of great violence would occur, and destruction to life and property ensue.

Although, of course, the area here indicated is quite variable in extent, yet it possesses the decided advantages of definiteness, familiarity to the people who are interested, and brevity of expression in rendering a concise despatch. The local signs of tornado-development are certain, easily observed, and well defined. With the people well informed on these points, and there is no reason why they should not be, the prediction of conditions favorable to local storms, issued from some central meteorological office, would, if successful, supplement the local signs with beneficial results. Failures in the official predictions would not only bring out more distinctly the importance and reliability of local signs, thus creating an interest in their careful observance, but would obviate the occurrence of serious results when wrong predictions were made, as the people would test their trustworthiness by appeal to the "local signs."

With the appearance of every new problem in science, especially if its solution involves the welfare of mankind or any great number of people, there is made the most strenuous effort to obtain deductive results, without due regard to proper methods of investigation. This is all quite in accordance with the inclination of human nature frequently to want without reason, but the true scientist knows that such demands cannot be complied with in safety.

People clamor for adequate means to destroy the tornado-cloud by a single blow, sometimes that can act with the rapidity of the electric shock; and because the article cannot be supplied in order, in quantity, and in style, to suit customers, we are informed by some critics that investigation thus far has been fruitless, and that our efforts to expose the nature and origin of tornadoes are the mere vapourings of a vivid imagination.

In this age of inventions and glittering geniuses, it is not surprising that the sufferings and the necessities of the tornado-stricken people have received attention; but, as usual, such attention has been more to the profit of the scheme and schemers than to the advantage of those whose credulity made them the victims of an overweening confidence. The festive and irrepressible lightning-rod pedlar has appeared upon the scene, and offers with great gusto a beautifully wrought metallic rod, to be attached to buildings with gilt fastenings, terminating near the chimney or cupola with a resplendent brass rooster or other decoration, which, while serving the purpose of a wind-indicator, is, together with the mysterious rod connecting it with the earth, a perfect protection against the tornado-cloud. How the result is obtained is a secret of the inventor. The purchaser must not inquire into the nature of this mystery, as his success with the venture depends solely upon an abiding faith and the requisite shenels.

There are other plans and devices deserving of a little more recognition, but they are wholly wanting in the essentials that shall make them reliable and capable of practical application at the moment of supreme danger. Among these may be mentioned (1) an arrangement to explode an underground magazine by electricity when the tornado-cloud approaches a town, a mill, or any group of buildings to be protected, the explosion to take place while the cloud is passing over the magazine; (2) an arrangement of high poles, electrically connected with each other and the earth, and covering about an acre of ground, the top of the poles to be furnished with long, sharp metallic points, so as to draw off the electricity of the tornado-cloud, and thus dissipate its energy at once, upon reaching the field of poles; (3) a cable to anchor a building safely against the fiercest tornado, and an insurance policy to cover all damages that may occur from the cable giving way; (4) an arrangement to keep kegs of gunpowder in a properly protected place to the south-west of the building, and, upon the approach of the tornado-cloud, courageous men to take out the kegs and place them in the path of the approaching cloud, the powder to be fired at the right time to destroy the cloud; (5) an arrangement to construct immense stand-pipes of heavy wrought iron, about five hundred feet high and one hundred feet in diameter, these pipes to be placed upon heavy masonry piers about ten feet high, and so constructed as to permit a free circulation of the air underneath, and upward through the centre of the pipe. The plan involves the erection of a considerable number of these pipes in the tornado regions, the requisite number to be determined by experience. It is expected that these great pipes will serve as vent-holes for the harmless escape of whirling eddies in the atmosphere, which otherwise might develop into destructive tornadoes. It is further claimed that these pipes may serve to increase the rainfall at any place by causing, artificially, the upward rush of a large volume of air, the moisture contained therein being condensed by the cold of elevation. The initiatory upward movement at the base of the pipe is induced by an open fire built on the ground, within the pipe and near the centre of the base. Of course, the physical principle involved is the upward movement of heated air, and the inrush, at the point of inception, of the surrounding cooler air, thus giving rise to an upward flow of more or less power, according to the amount of heat applied and the volume of air affected.

The limits of this paper will not permit of a critical discussion of the merits of the various mechanical devices for the destruction of the tornado-cloud, or even to mention them all. Suffice it to say,

that the writer is of the belief that all efforts directed toward the accomplishment of the destruction or dissipation of the tornado-cloud by any known and practicable means, will fail of realization.

Mechanical appliances are wholly incapable of successfully coping with the forces of the tornado, which, unlike the whirlwind and waterspout, arises from the unstable state of the atmosphere in the cloud region, where the tornadic gyrations commence, and are afterwards propagated downward to the earth's surface. The tornado is controlled by the operation of forces far above the ground.

A RIVER-PIRATE.

THERE is a little river-pirate in eastern Pennsylvania unsuspected by its rural neighbors. It is in a quiet, well-watered farming district, where the streams, as a rule, are bent only on minding their own business, and not interfering with their fellows; and yet one of them is a confirmed pirate, and goes on unhindered in its robbery.

The pirate is Déer Run, and its victim is the north-east branch of Perkiomen Creek. The head waters of the latter have been captured, and led away from the basin where they were born and passed their youth, and thus diverted to swell the surreptitious vol-

ume of the intruder. The affair has happened in this way. The country hereabout was in ancient times a surface of faint relief, at a lower stand than now, traversed by idle streams; but, in consequence of elevation to a greater altitude, the streams have revived their lost activities, and set to work to sink their channels and open out their valleys in the process of reducing the land to its proper level again, even with the sea; for land finds its level, like water, but more time is required before the level is assumed. The streams that drained the country when it was elevated adopted such faint inequalities as they then found for their first settlement, and have since been engaged in perfecting their courses as best they could, cleaning them out, deepening them, and adapting them most exactly to the best transportation of land-waste. In the processes of adjustment thus called forth, every stream struggling for its own existence, it sometimes has happened that a stream with steep head waters has seized drainage area from the flat-lying head waters of an adjacent basin; because, other things being equal, the waste of the surface is fastest on the steepest slopes, and hence the steeper streams have gnawed more quickly into the land-mass than the flatter ones, and the divide between a pair of contesting streams has consequently been pushed in the direction of the fainter descent.

The abstract possibility of this process cannot be questioned; but one might well hesitate before accusing so innocent-looking a stream as Déer Run of such underhand designs. Yet the evidence of its piracy is too direct to be doubted.

In the first place, the region that the two streams drain has been

accurately surveyed by the Philadelphia Water Department, and the maps thus secured have been published by the Geological Survey of Pennsylvania. The facts of the case are thus brought clearly before the world, after long remaining in unsurveyed obscurity. It is from one sheet of these maps that the accompanying figure has been traced, omitting the wooded areas and dwellings. The smaller map in the corner indicates the location of the district under discussion in the south-eastern corner of Pennsylvania, north of Philadelphia and west of Trenton. In the next place, it is to be noted that the slope of Déer Run from the divide *DD* is twice as steep to the north-east as is that of its victim to the south-west. Déer Run descends sixty feet in a mile at its head; the Perkiomen branch descends only thirty feet in the same distance. Again: it appears that the two streams, flowing on the same line but in opposite directions, both follow the same bed of shaly sandstone in the rock formation (triassic) that underlies the district; there is, therefore, no inequality of structure on the two sides of the divide to determine a difference in the rate of head-water weathering. In so short a distance as a mile or two, it cannot be thought that there is any difference in rainfall or other climatic element of significance; and, if exposure to sunshine be a factor of value in aiding the denudation of a surface by strengthening the diurnal variations of temperature in the soil and increasing the number of winter thaws, this advantage would be with the Perkiomen. Leaving this aside, it appears, that, except for difference of slope, the streams are in similar conditions, and any inequality in their action must be referred to the control that the slopes exert. As the control exerted by the slopes is distinctly in favor of Déer Run, we must conclude, that, if a patient observer should take his stand on the higher ground near by, he would certainly see the divide *DD*, migrating, rather slowly to be sure, to the south-west. After a time the uppermost side-stream of the Perkiomen branch, *aa*, would be tapped by the insidious operations of the pirate; and, powerless to withstand the temptations of a more facile descent, it would turn from its parent to join the volume of its captor. In time another side-stream, *bb*, would be led astray; and thus Déer Run would extend its territory at the expense of its more inert neighbor, and the divide would in time be shifted to *BB*.

Now, it is noticeable that all tributaries thus acquired by the pirate would enter the head of its main channel in a back-handed manner, like the barbs at the point of an arrow, indicating by this abnormal arrangement their early training in accordance with the habits of the Perkiomen family, where they were brought up. But if this process is going on now, we must be persuaded that it has been in operation in earlier times also, and that results of the kind now predicted for the coming ages should already be visible as the product of those gone by. Such is undoubtedly the case. Déer Run bears at its head at least three small side-streams, which still manifest in their directions the clearest indications of Perkiomen habit; and thus it must stand convicted not only of piratical intentions for the future, but of piratical practice in the past.

If the reader should, perchance, be seriously inclined to geographic study, he may find many accounts of this kind of interaction among rivers in the writings of recent authors. Gilbert has considered examples of the process in our Western Territories; Löwl and Philippson have pointed out a number of instances among the rivers of Europe; and Heim has shown how the picturesque little lakes at the head of the Engadine result from the capture of head-water streams by the steep-sloping Maira from the more steady-going Inn. As our intimate acquaintance with the geographic development of our country is furthered by the publication of good topographic maps, we shall undoubtedly find many cases of head-water adjustments. The Atlantic-Mississippi divide, from Pennsylvania to Alabama, should be especially rich in them.

Yet, if what is one man's food is another man's poison, it may be that what is one man's crime is another's virtue. It is only in false allegory that we can blame Déer Run for having taken what once belonged to the Perkiomen; and instead of calling the capture of head waters a piratical act, which at best is but an *ad captandum* term, it should better be regarded as a sharing of another's burden of labor, and a willing assumption by the more active stream of its fair proportion of the work to be done by the whole river system to which it belongs. Instead of gauging the disposition of streams by

likening them to human pirates, and berating Deer Run for what it has done, let us look at the affair from the point of view that a well-disposed river would take.

When this district was lifted from its former lowly estate, the streams found a new task set before them. They at once set to work at it with the best disposition in the world. But, in their immaturity, they accepted without question such guidance as the faint relief of the surface afforded, only to discover later on that the primitive division of territory was unadvisable as a permanency, because it was not adapted to the best accomplishment of the work assigned to them. It is found that a re-adjustment of boundaries, in certain cases, will allow a more economical transportation of land-waste to the sea by better-arranged channels; and, when this becomes apparent to a stream, it at once obeys its new opportunity, whatever force of habit it may theretofore have had. If the ideal of a stream's life were always to persevere in the channel that it at first selects, this readiness to change its course would be called fickleness; but when we perceive that the true ideal of a stream's life is to carry towards the sea its full share of the waste of the land that its river system drains, then we may recognize a virtuous willingness to the performance of duty in this immediate forsaking of an old course, and adoption of a new one, where its work can be done better and quicker. It is the unwisdom of youth that is thus corrected by the better choice of maturity, and many a river has thus improved its early ways. It is undoubtedly true that Deer Run has taken something of what once belonged to the Perkiomen, but it was not seriously that the name of a river-pirate was given to it.

W. M. D.

A POPULAR OBSERVATORY.

A FEW months ago a company was formed in Berlin, the aims and purposes of which are well worth being widely known. The company is named "Urania," and it was established for the purpose of diffusing the interest in the phenomena of nature. Some of the most prominent German scientists are the promoters of this enterprise, the plan of which originated with the distinguished astronomer Professor W. Foerster, who explains the objects of the company as follows: The object of the society is to promote knowledge. In order to inculcate knowledge, it is necessary to educate man to use his mental powers. Therefore institutions for the diffusion of knowledge can only be successful when they try to teach how to use one's mental powers. The society has limited its work principally to astronomical, geographical, and physical phenomena, and for reaching its object has established a great popular observatory, which will be a model for all similar institutions, and publishes a journal, *Himmel und Erde* (Berlin, H. Paetel), which is beautifully printed and illustrated, and gives, in a popular form, reports on astronomical and geographical phenomena and questions.

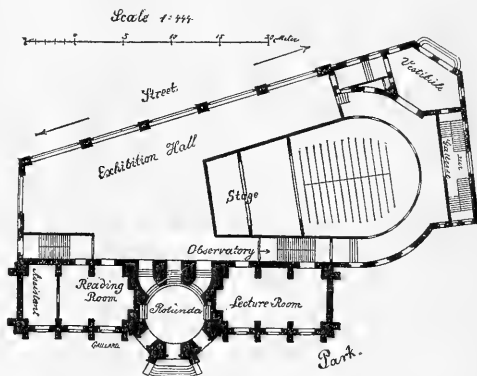

The popular observatory, of which we reproduce the plan, is divided into three sections, — the rotunda, which forms the foundation of the observatory proper; the large hall, in which instruments and microscopes are exhibited; and the scientific theatre. It is the plan of the founders of this institute to benefit the general public, which embraces uneducated as well as educated persons. Therefore the methods of instruction are varied according to the intelligence and education of the various classes. The scientific theatre forms the lowest stage, on which the results of exact investigations are presented in as attractive a form as possible, in order to give a stimulus to intelligent observation. Solar and lunar eclipses, comets, and meteors are shown to the spectator; the scenery representing beautiful and characteristic landscapes of the parts of the globe in which these phenomena were seen. Thus the desire is aroused to understand the origin of these phenomena, which, only a few centuries ago, were considered as forebodings of evil. These views are accompanied by lectures calling attention to the peculiarities of the phenomena observed on the scene. Among others, a series of astronomical panoramas has been prepared for the purpose of explaining the phenomena of solar eclipses.

At the commencement of the lecture stage represents a landscape near Berlin, at the beginning of the total eclipse of Aug. 19, 1887. At that time unfavorable weather prevented the remarkable

phenomena from being seen, to which attention had been called in newspapers and journals. In the theatre all phenomena of the eclipse will be shown as they would have happened in clear weather. First the landscape will be seen in the light of the early dawn; then the sun will slowly rise on the horizon in the shape of a crescent between purple clouds. The crescent grows narrower rapidly until the dark shadows of the eclipse appear. After two minutes the character of the illumination changes again, and soon the landscape is seen lighted by the clear sun.

While the lecturer explains this phenomenon, the scene changes, and the spectator is transported to a place at some distance from the earth. The huge globe rotates in front of the zodiac, whose signs form the background. The moon, moving through the sunlight, throws its shadow upon the planet, and it is seen crossing the continent of Europe. It is at once understood how the eclipse originated. We continue our journey and reach the moon. We see its desolate mountain ranges. There is deep night in the valleys, while the summits of the mountains are lighted by the rising sun. On the starry sky the earth is seen, giving some light to the parts of the moon over which the sun has not yet risen. On the earth a small dark dot is seen, the point of the shadow of the moon, and its track shows the region where the eclipse is visible. Our journey is continued toward the sun and the planets, the surfaces of which are shown according to the result of the most recent investigations.

A higher stage of instruction is given in the exhibition hall, in which instruments, apparatus, and arrangements of various kinds,

PLAN OF THE POPULAR OBSERVATORY IN BERLIN.

are exhibited, for the purpose of explaining physical phenomena. The composition of sounds, particularly those of speech, are exhibited. The wonderful phenomena of light; its enormous velocity; its composition of numerous colors, which makes nature appear so beautiful; the wonders of the spectroscope, which betrayed the chemical composition of the celestial bodies, and is at present used in many industries, for instance, in the Bessemer process, and in the examination of wines and other liquids regarding their adulteration; the phenomena of polarization and their application in the manufacture of sugar, — all these will be shown and explained to the visitor. In another section of the hall the phenomena of heat will be explained. Models of machines will be exhibited here in great numbers. In still another part of the hall electricity and magnetism, and their extensive applications in manufactures and as a means of rapid communication between distant places, will be shown. Furthermore, fifty microscopes will be placed in this hall, in which the use of this powerful help to scientific investigation will be explained.

Instruments of precision will be exhibited in the same hall. From the latter a staircase leads to the observatory, passing the lecture-room. Here astronomical and microscopical objects will be shown by means of the lantern, and a lecturer will call attention to the characteristic features of each object before it is seen through the telescopes and microscopes.

The observatory of the Urania will be furnished with a number of small instruments; but, in addition to these, it will have the most powerful telescope of Berlin. The lens of the great refractor will be twelve inches in diameter, while the length of the telescope is to be five metres. The dome is eight metres in diameter.

The establishment of this grand institute marks a new departure in the methods of popularizing the natural sciences, and its influence cannot fail to be wholesome. It will educate the masses to an intelligent observation of natural phenomena.

SCIENTIFIC NEWS IN WASHINGTON.

Irrigation in California. — The Nucleus of a "Zoo." — Mounds of Ohio. — Triple Births in the Human Race. — The Talking-Machine in Use. — Where Will It Go Next?

Irrigation in California.

MR. WILLIAM HAMMOND HALL, State engineer of California, addressed the National Geographic Society on Friday evening last, on irrigation, particularly irrigation operations in California. It appears that the first work of this kind within the State, subsequent to that of the early mission fathers, was undertaken by a band of Mormons in the San Bernardino valley, in 1852.

Of the total area of California perhaps one-third is susceptible of sufficient cultivation to sustain a moderately dense population without the aid of irrigation, while one-third will not sustain a sparse population without the aid of irrigation. The principal regions of irrigation in the State are the great interior valley, the southern valley, and the coast plain of the south. By a comparison of the relative amount of rainfall in the older countries of Europe with that of California, and from the peculiar character of the soil, Mr. Hall showed that the relative necessity for the artificial application of water is far greater in California than in these countries, the annual rainfall being much less, and the character of the soil and rate of evaporation quite as unfavorable.

There are in California about 750,000 to 800,000 acres actually irrigated each year, representing what would ordinarily be called an irrigation area of 1,200,000 acres, and there are reasonably within reach of existing canals 2,500,000 acres. The methods of applying water differ very widely with the differing conditions in the various irrigable areas. Much has been done by individual effort in regions where the problem of diverting water from the streams is comparatively easy; but there remain a large number of streams presenting difficult problems, the waters of which can only be utilized by the expenditure of immense capital and the operation of extensive works. Land values in the valley have increased from \$1.25 per acre, prior to the introduction of irrigation, up to \$250 and even higher values, merely by having water rights attached. Much is expected from the investigations on this subject which Congress has recently authorized to be prosecuted.

The Nucleus of a "Zoo."

The Department of Living Animals at the National Museum attracts greater crowds of visitors than can find comfortable standing-room in the animal building, and furnishes one of the strongest arguments that could be made on the necessity of a great national zoological garden. Gifts and deposits have been coming in in such number, that the museum authorities have found it necessary to decline a number of valuable objects, such as a lioness, aoudad, black leopard, camel, and ostrich, because the institution is positively unable to provide for their accommodation. The total number of live animals, birds, and reptiles received up to date is 281. One of the latest arrivals is a great rarity, a Rocky Mountain sheep from north-western Montana, the gift of Mr. George Bird Grinnell, editor of *Forest and Stream*. It has attracted thousands of visitors, and is at present in fine condition. So far as known, it is the only specimen of the species now alive in captivity.

Mounds of Ohio.

At the instance of Dr. Cyrus Thomas, Mr. Reynolds of the Bureau of Ethnology has recently conducted an exploration of one of the most interesting mounds in Ohio; namely, the truncated pyramid associated with the system of enclosures opposite Bourne-

ville, in the Point Creek valley. These enclosures belong to the type comprising true circles and equilateral squares. It proved to be a burial-mound in which two series of circular upright palings, thirty-six feet in diameter, constituted a pre-eminent feature. These indicated successive erection and use, as the mound was from time to time enlarged. The skeletons found were all interred systematically within these wooden palings upon the different sand-seams at different depths. The burials were evidently successive or periodical. None of them could have been intrusive, since the stratification above them was not disturbed. Many interesting specimens, comprising pottery, stone pipes, shell beads, and grooved bone implements, were found deposited with the various skeletons. These and other features that were observed, will, it is said, prove eminently helpful in the solution of the questions relative to the age and builders of these interesting works.

Triple Births in the Human Race.

Some interesting data respecting the frequency of triplets in the human race are being collected and elaborated by Dr. B. Ornstein, late surgeon-general of the Greek army. While on an inspection tour through western Greece, he discovered the fact that triplets are more frequently found there than in any other portion of that kingdom. Great difficulty is experienced, however, respecting information as to the age reached by either or all of the children.

It is desirable therefore, for the purpose of careful study of this subject, to gather information based upon the following: viz., (1) all well-authenticated instances of triple births, and in how many of them the three children reached the age of two (or more) years; (2) the number of cases in which two of the triplets survive one year, or longer, or in which one of them reached the age of one year or more.

Any information pertaining to this subject will be gratefully received by Dr. Ornstein, Athens, Greece; or communications will be forwarded if sent to Dr. W. J. Hoffman, Bureau of Ethnology, Washington, D.C.

The Talking-Machine in Use.

The Geological Survey is the first of the government offices to adopt the graphophone for service. Major Powell is supplied with one of these wonderful little listening and talking machines, and he takes it home with him, and talks to it as the necessity arises or an idea strikes him. In his absence an intelligent boy or girl can evoke a repetition of his monologue, and commit it to paper.

Where Will It Go Next?

The apparatus of the Life-Saving Service which has attracted such deep interest in the Cincinnati Exposition is home again, and safely under shelter. Mr. S. I. Kimball, in charge of the bureau, does not wish to return it to the bare and distant loft of the Treasury Department, where for many years it has been an object of curiosity to visitors, but will await the assignment to it of convenient quarters, where the property can be properly protected.

BOOK-REVIEWS.

The Teachers' Psychology. By A. S. WELCH. New York, E. L. Kellogg & Co. 12°. \$1.25.

THIS work consists of two distinct parts, the first being a treatise on the intellectual faculties, and the second an essay on the proper method of educating them. The author begins with a general view of the mind as a whole, with its three functions of thought, feeling, and action, but afterwards confines himself to the operations of the intellect. This psychological part of the book cannot be pronounced very successful. Mr. Welch's philosophical standpoint seems to be that of the Scottish school; but he cannot be compared with the standard authors of that school in his method of treatment. He takes a surface view of his subject, and, besides, is often lacking in accuracy. Thus, the term "concept," which has always been used to denote a general idea, is employed in this work for both general and particular ideas. Mr. Welch's view of memory is also peculiar, for he includes in it the act of acquiring knowledge as well as the acts of retaining and recalling it. The second part of the work is of a better character, and lays down

certain principles of education to which little exception can be taken. The author holds that education ought to conform to the course of mental development, each study being introduced at the time when the mind is best fitted to pursue it, and hence that studies requiring a high degree of abstraction and close reasoning should not be taken up until after the simpler and more concrete subjects have been mastered. He gives some examples of wrong arrangement of studies, and some suggestions as to the proper mode of teaching certain branches; and, though there is nothing new in his theories, teachers may find his presentation of them worth examining.

AMONG THE PUBLISHERS.

In the February *Wide Awake*, "Forty-eight Hours a Day" will interest all astronomically minded young folk, and their elders as well; "An Old-fashioned Boat" is an interesting chapter in the progress of invention, by Ernest Ingersoll; Mrs. Sallie Joy White, in her chapter on "The Use of the Oven," tells how potatoes are baked in the Boston public schools; Mrs. Goddard Orpen gives the history of the famous Spanish crown pearl, the *Pelegrina*; and Professor Starr, in his geological series, describes some of the gnawings of "The Tooth of Time."

— P. Blakiston, Son, & Co., of Philadelphia, have just ready "A Text-book of Operative Dentistry," by Professor Thomas Fillebrown of the Harvard Dental School, and a second edition of "A Handbook of Diagnosis and Treatment of Skin Diseases," by Dr. Arthur Van Harlingen. They have nearly ready "A Surgical Handbook," by Professor F. Mitchell Caird and Dr. C. Walker Cathcart, of the University of Edinburgh, thoroughly illustrated, and printed in a convenient shape for carrying about.

— W. H. Lowdermilk & Co. will publish in the course of a week "Matthew's Guide for Settlers upon Public Lands of the United States," intended for all having business before the district land office and the Department of the Interior. It is prefaced by a map of the United States, showing the thirteen original States, with the territory subsequently acquired, giving dates and sources of acquisition and the various State and territorial laws regarding real property, and how under United States laws it may be acquired. The author was late assistant chief of the preemption division, General Land Office.

— G. P. Putnam's Sons announce among their earlier publications for 1889 the following: the first volume of the letter-press edition of "The Writings of Washington," edited by Worthington C. Ford, which will be uniform with the previously published sets of "Hamilton" and "Franklin," and be completed in fourteen volumes, limited to 750 sets; a second edition, revised and enlarged, of "The Best Books: a Reader's Guide to the Choice of the Best Available Books in All Departments of Literature, down to 1888," compiled by William Swan Sonnenschein; and "English Wayfarer's Life in the Middle Ages" (fourteenth century), by J. J. Jusserand, translated from the French by Lucy Toulmin Smith. The author has supervised the translation, and has added about a third of new matter, so that the volume differs materially from "La Vie Nomade." The original work was published without illustrations, while this English edition, which is issued in London by T. Fisher Unwin, will be elaborately illustrated from a number of rare designs that have not previously come into publication. Besides these, they announce "A Manual of Oriental Antiquities," including the architecture, sculpture, and industrial arts of Chaldaea, Assyria, Persia, Judea, Phoenicia, and Carthage, by Ernest Babelon, librarian of the Department of Medals and Antiquities in the Bibliothèque Nationale of Paris, translated and enlarged by B. T. A. Evetts of the Department of Egyptian and Assyrian Antiquities of the British Museum, with 250 illustrations; "From Japan to Granada: Sketches of Observation and Inquiry in a Tour round the World in 1887-88," by James Henry Chapin, D.D.; "Business," a practical treatise, by James Platt, reprinted, under arrangement with the author, from the 75th English edition; in the Knickerbocker Nuggets, "Ancient Spanish Ballads," historic and romantic, translated, with notes, by J. G. Lockhart, with sixty illustrations by Allan, Roberts, Harvey, and others, and "The Wit and Wisdom of Sydney Smith;" and in the Questions of the Day

Series, "Outlines of a New Science, a Study of Industrial Conditions," by E. J. Donnell; "Politics as a Duty and as a Career," by Moorfield Storey; "The Plantation Negro as a Freeman," observations upon his character, conditions, and prospects in Virginia, by Philip A. Bruce.

— D. Lothrop Company will publish shortly a story by a New York lady which is said to be a refutation of much of "Robert Elsmere;" and a volume of stories by H. H. Boyesen, called "Vagabond Tales."

— T. Y. Crowell & Co. have in preparation, for the use of schools, an abridged translation of Duruy's admirable "Histoire de France," under the charge of Professor J. F. Jameson of Brown University. They announce for early publication Bourrienne's "Memoirs of Napoleon Bonaparte" in four volumes. They will be handsomely illustrated, and will contain all the critical and biographical and historical notes which add so much to the value of the latest English edition.

— D. Appleton & Co. announce for this week, "Nature and Man," a series of essays, scientific and philosophical, by the late William Benjamin Carpenter, with an introductory memoir by J. Estlin Carpenter, and a portrait of the writer of the essays. The volume also includes a few passages from Dr. Carpenter's earlier writings, prefixed to illustrate the prior stages of his great labors for physiological psychology.

— Henry Holt & Co. will publish shortly a book on the American Revolution, which will furnish not only novel but highly curious matter. In his researches among the French archives, Mr. John Durand, the translator of M. Taine's "French Revolution," found many documents relating to the United States which were of the greatest interest. These papers have been translated by Mr. Durand for the first time, and are edited by him. The work will throw light on various episodes of the American Revolution as well as on the characters of the men who took part in it. The peculiar rôle played by Beaumarchais, the cabal against Washington and Franklin, the secret sessions of the Continental Congress, of which no detailed account has come down to us, together with the social aspects of the country while the Revolution was in progress, will all be presented.

— Harper & Brothers have just published a volume on "The Government of the United States," by W. J. Cocker, A.M., primarily intended as a text-book for public schools, but also calculated to serve as a clear and concise reference manual upon the Constitution. The author presents the influences and conditions which rendered the Constitution a necessity, and describes the powers and limitations of our form of government. The numerous references to more extensive works on the subject make the book a valuable guide in prosecuting further a study of our institutions. Three other books also just ready are: "Modern Science in Bible Lands," by Sir J. W. Dawson, which presents a study of such points of the geology and physical features of Italy, Egypt, and Syria as might throw light on their ancient history, and especially upon the history of the sacred scriptures; "Our English," by Professor Adam S. Hill, which contains novel and sensible suggestions for the proper teaching of the language in schools and colleges, and reviews "Newspaper English," "English in the Novel," "Pulpit English," and "Colloquial English;" also an edition in book form of Charles Reade's "Bible Characters."

— The two latest issues of the *Forum* contain articles by ex-President Andrew D. White of Cornell, on the need of new universities in this country, and particularly on the project for a great central university at Washington. In the January number the writer speaks of the present position of the higher education in America, and of the rapidly increasing demands on the existing universities. He notes the fact that a process of separation is in progress among our institutions of learning, and that a few of them are developing into real universities, while the remainder are tending to become intermediate colleges, holding a position between the universities and the public schools. Real university instruction, he maintains, can only be given in large and liberally endowed institutions, and he believes that we need one or two such institutions of a higher order than any we now have. The most suitable

places for such an institution are New York and Washington. With regard to the former, Columbia College has excellent facilities for supplying the need; but in Mr. White's opinion "the majority of its trustees have long since proved themselves blind to their opportunities." Hence, in a second paper in the February number, he favors the founding of a new university at the national capital, which he thinks the best place in the country for the purpose. The advantages offered by Washington consist partly in the number of able and learned men resident there, whom the university could employ as lecturers or teachers, but still more in the libraries already established in the city, containing over a million volumes, and in the extensive laboratories and other means of investigation maintained by the government. Mr. White believes, that, if the necessary funds could be obtained, a university could be established at Washington which would not only have a powerful influence on the higher education of the country, but would help to raise the tone of political life at the national capital. As to this latter point however, the question arises whether the politicians would not be more likely to exercise a deleterious influence on the students. Besides this article by Mr. White, the February *Forum* contains ten other papers on a great variety of subjects. Mr. W. F. Lilly has one on "The Foundation of Ethics," in which he takes strong ground against the evolutionary theory of ethics as taught by Herbert Spencer, maintaining that it is not only false, but practically pernicious, and that it is already exercising a baneful influence on moral conduct in art, journalism, politics, and other departments of action. What its effects and tendencies are, he promises to state more fully in succeeding articles. Judge Alfred C. Coxe has an important paper on "Relief for the Supreme Court." He alludes to the fact that the Supreme Court of the United States is three or four years behind its docket, and then suggests that the court might catch up with its work if the judges were relieved from circuit duty, which would enable them to sit at Washington two months longer than they do now, and if the practice of reading opinions, which now occupies one day in each week, was abandoned. The other articles we have not space to notice. The *Forum* has taken its place as the foremost magazine for general discussion in the country; but it seems to us, that, if some of the papers it prints were longer and more elaborate, its usefulness would be enhanced.

LETTERS TO THE EDITOR.

*. *Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith.
Twenty copies of the number containing his communication will be furnished free to any correspondent on request.

The Baconian Method in Science.

In the nineteenth aphorism of his "Novum Organum," which forms the second part of his "Instauratio Magna," Lord Bacon observes that there are two possible methods for investigating and discovering truth. The one, he says, flies at once from particular observations to axioms of the broadest generality, and from these principles and their immutable verity it scrutinizes and discovers its mediatory axioms or propositions leading to subordinate truths. The other method from particular observations calls forth axioms in a continuous and gradual ascent, so as at last to attain truths of the broadest generality. The former of these methods, he says, is the one in use; the other is new and untried.

The former method is familiarly known as the deductive method. This movement of thought was thoroughly studied and expounded by Aristotle, and is well understood. Lord Bacon opposed his "new and untried" method to the old in this specific feature, that the old or deductive method moved characteristically from the general to the more specific, whereas his new method proceeded from the particular, and advanced, step by step, to the general. Obviously this new movement of his is simply what is known in recent logical science as generalization, — the amplification of a subject-notion or concept. It does not appear from Lord Bacon's writings that he concerned himself at all about the special differences between logical generalization and logical induction. He only insisted that scientific study should in the future unite the two methods, — the old, which moved from the general to the particular, with the new, which moves from the particular to the general.

Nor does he appear ever to distinguish the movement of thought in proper generalization, which confines itself to the subject-notion, from that known in logic as determination, which is the amplification of the attribute-notion; just as the old method did not distinguish between the two movements in the reduction of a concept or notion, — between division, which was applied to subject-notions, and partition, which was applied to attribute-notions.

These movements of thought are fundamental movements, and differ widely from one another in their respective natures and their governing laws. It is as important for the facile and successful prosecution of scientific study in any field of knowledge that they be familiarly known, and be reduced to ready use, as it is for the successful prosecution of mathematical studies that the fundamental or ground rules of arithmetic be mastered for accurate, and, as it were, instinctive application whenever needful. Popular discourse may, perhaps, be pardoned for some looseness in the use of the technical terms and phrases of science; but discussion professedly scientific, and claiming for itself something of the certitude of genuine knowledge, should not ignore these ground rules of scientific knowledge, nor confound them one with another. Widely as they differ, they are alike serviceable for scientific uses; they are of equal validity; they are equally intelligible in their essential nature and in their applications. This is evident from the most cursory exposition.

All complete thought is quantitative. This attribute is revealed among the most fundamental properties of thought. But in quantity, which is but the attribute otherwise known as that of "whole and parts," as we conceive of an object quantitatively when we conceive of it as a whole having parts, extensive or intensive — in quantity there are three, and only three, conceivable relationships of the highest or most generic order; viz., (1) that of whole to part, (2) that of part to whole, and (3) that of part to part. There are, accordingly, only three corresponding movements of thought possible in this relationship: (1) deduction, (2) generalization, and (3) induction. We pass over here the distinctions already indicated as required in accurate science to be made on account of the diverse character of notions as subject-notions or as attribute-notions, and use the familiar designations of the different movements. Deduction moves from whole to part; generalization, from part to whole; induction, from part to part.

Notwithstanding this manifest, and to a large extent familiarly recognized, distinction between these fundamental movements of thought, there is a common loose or faulty use of the terms which properly designate them that is greatly to be deprecated. Particularly is this observable in the case of the term "induction" and its paronyms. For example: "an inductive study of the mind" or "of the Scriptures" is every now and then proposed, when a true inductive study obviously could never have been intended. And even among professedly scientific thinkers are to be detected not infrequently the most shadowy and illusive or even positively false notions of induction and inductive science. Modern science boasts of itself as being characteristically and distinctively inductive, while it would be difficult to find in its work any conscious recognition of the essential character of this fundamental movement of thought. In truth, even logical science has but very imperfectly apprehended it, although the most familiar movement in every-day life. The child induces from one experience from touching the flame what a repetition will cause, and confidently expects to find in the next flower he plucks something of the figure or color or fragrance that he has found in the one he has already gathered. Moreover, the exact character of the movement was scientifically grasped and indicated many centuries ago by the father of logical science. He did not elaborate the exposition of the inductive movement as he did that of the deductive movement; but he exemplified it perfectly in the first book of his "Prior Analytics," c. xxv. (Tauchnitz edition), where from "bileless" and "long-lived" being both attributes of "man," "horse," etc., he infers that the presence of "bileless" involves that of "long-lived." The principle, he says, is this: if any two attributes as parts belong to the same whole, the existence of either one in any case determines the existence of the other. We might state it thus: from any part of a given whole we may infer or induce any complementary part.

Insurance.

DELAY IS DANGEROUS.

We call attention to the new form of Accident (indemnity) Insurance policies, which are written by the Merchants' Casualty Insurance Association, 21 Park Row, New York City, John S. Purdy, Secretary. These policies cover weekly allowances of from \$10 to \$25, according to occupation, at a cost of only \$6 a year exclusive of the cost to join, which is \$2 payable once only. The public, as a rule, carry life insurance, and the ordinary accident policies issued by companies, paying a sum in case of death, is not so desirable as one of these indemnity policies in case of accidents, which are so plentiful in this fast age with its railroad horrors, fast driving, electric wires and other countless forms of dangero to which the public is constantly exposed. The fact of the Association having no unpaid claims, and its having just passed an examination by the Insurance Department of New York State, shows that the management is liberal with its policy-holders and conservative in its action. The Association also desires to secure energetic Agents in every village and town, to whom territory and favorable terms will be given.

Hon. ALBERT H. HORTON (Chief Justice, Kansas Supreme Court), Topeka, Kan., Pres't.

7% Guaranteed Farm Mortgages 7%

The Guaranty Investment Company makes loans upon fertile farms in the choicest portions of Kansas and Nebraska and has adopted the policy of sending a Committee of its Investors each year to examine its loans and methods of business.

The Committee this year consisted of PROF. A. H. BERLIN, Principal of the High School Montrose, Pa., and MAJ. THEODORE L. POOLE, Ex-U. S. Pension Agent, Syracuse, N. Y. Both of these gentlemen are persons of the highest character and have the confidence of the Communities in which they reside.

The Committee has recently returned and has made a very interesting Report upon the general development of Kansas and Nebraska as well as the business of the Company. The Company will be glad to send this Report to any address.

The following names are taken from the long list of Investors in our Mortgages:

SCOTT'S EMULSION

OF PURE COD LIVER OIL AND HYPOPHOSPHITES

Almost as Palatable as Milk.

Containing the stimulating properties of the Hypophosphites combined with the Fattening and Strengthening qualities of Cod Liver Oil, the potency of both being largely increased,

**A Remedy for Consumption.
 For Wasting in Children.
 For Scrofulous Affections.
 For Anæmia and Debility.
 For Coughs, Colds & Throat Affections.**

In fact, ALL diseases where there is an inflammation of the Throat and Lungs, a WASTING OF THE FLESH, and a WANT OF NERVE POWER, nothing in the world equals this palatable Emulsion.

SOLD BY ALL DRUGGISTS.

SCIENCE

FRIDAY, FEBRUARY 15, 1889.

SOME EXAMPLES OF MEXICAN PRE-COLUMBIAN ART.

DURING the winter of 1881 I collected on the site of the ancient city of Teotihuacan ("the place of those who adore the gods"), about forty kilometres north-eastward from the City of Mexico, and within the great valley enclosing the capital, several hundred objects of moulded and modelled terra-cotta. Some of these I gathered from the heaps of *débris* that mark the locality of this "former religious centre of the Nahuan nations;" but the greater number were secured, generally six or eight in a place, by visits to the houses of the simple agricultural people, who had found them while cultivating the neighboring gardens and fields. The soil in which these objects had reposed for a period of unknown duration, is spread around the two great *teocalli* of earth and broken stone that rise conspicuously above a broad fertile plain. The Pyramid of the Sun, the principal of these prehistoric structures, is prob-

displayed in the great museums in Europe and on this continent to modern apprehension are generally meaningless or grotesque. Often two round cavities stand for eyes; a crooked ridge laboriously furrowed out with stone tools is offered for an arm; or the action of the figure is so violent and crudely expressed, or the surface so overloaded with symbolic designs, that the original thought is lost to the observer of to-day, or seems the work of some unskilled and ignorant devotee. It is, however, not in the hard stone carvings that we can hope to find any adequate evidence of the mental capacity of the aboriginal sculptor. The plastic clay that abounds was all that he could desire for fixing and transmitting his conceptions. Indeed, it seems to me that no form of pristine thought should advance more rapidly and steadily toward excellence than that which may be expressed in clay. The artistic conceptions of the best minds, once formulated in this material, would be transmitted to following generations in the shape most readily comprehended, imitated, and improved, — a model and a stimulus for every succeeding artist.

2

1

3

ably the highest work of American aboriginal peoples. It overtops the celebrated mound of Cholula nearly fifty feet, and, with a base somewhat larger than that of the chief pyramid of Gizah, it rises 214 feet, nearly half the height of the Egyptian world-wonder.

The rains of many summers have furrowed the sides of this ancient temple into irregular ravines, through the aid of which, and by exercising a little care in selecting a zigzag path, I was able to ride my tough pony to the platform upon the summit.

Among the numerous fragments of terra-cotta obtained as above described, a large proportion are one to two inches in either dimension, and represent the human head or face. Many are reliefs broken, by the action of time or otherwise, from vessels of clay, or from figures more or less complete. These faces or parts of figures are often accompanied by elaborate ornaments, such as necklaces of beads, high head-dresses of feathers, and large ear-rings, all carefully moulded or stamped in the clay. Many pieces consist simply of heads attached to a short neck, without any evidence of having formed part of a more complete figure. From all the evidence in my possession, I conclude these objects belong to a date anterior to the Spanish Conquest. By some students a portion of the types are referred to the Aztec period; another portion, to the Toltec, or even to the pre-Toltec Totonacs; but into this discussion I shall not here enter.¹

The massive Mexican statues of basalt and trachytic lava that are

Out from the dull uniformity of primitive thought from time to time glows the light of a genius whose inventions, transmitted by poetry or tradition or the plastic arts to succeeding enlightened peoples, command from them the warmest sympathy and recognition, — a genius who, like him of "the wooden statue of Sakâra," is hailed as a worthy compeer by cultivated men of the ripest civilization. The student wandering among the conventionalized art-products of the oldest dynasties at Boulaq, stands amazed before this wonderful production of a mind that wrought in the dim twilight of the history of the human race. Thereafter he feels that the possibility always exists of detecting among the works of any unenlightened people isolated examples of a high art insight. The tools of the Sakâra sculptor were of a primitive character, and he sought the soft native wood as a medium for his productions: with still ruder tools at his command, the Mexican artist found the proper medium in the potter's clay that lends itself, with all its perfections, alike to the hand of the mound-builder and to the modelling tools of Canova.

The accompanying engravings represent faces that were selected from those found at Teotihuacan to illustrate the capacity of pre-Columbian Mexican artists. They have been reproduced, without retouching, by the direct process, from my photographs of the originals in the Metropolitan Museum.

No. 1 represents a fragment of terra-cotta engraved about one-third greater than the actual size. It is a portion of a larger clay object, upon which the remarkable face has been impressed by means of a carefully prepared matrix or stamp. This matrix was

¹ For a learned and valuable contribution to our knowledge of the "terra-cotta heads of Teotihuacan," see Mrs. Zelia Nuttall's illustrated essays in the *American Journal of Archaeology*, 1886.

in all likelihood formed of burned clay, like hundreds that have come down from the primeval potters of Europe and America, and was itself made by an impression from an original carving of clay or other substance. The face shows slight evidences of retouching: perhaps the expressive wrinkles over the right eye were added after the figure was impressed by the matrix.

The surface of many ancient Mexican vases is loaded with ornament, such as stamped or modelled faces and heads of men and animals. This fragment may have formed such an ornament; and if the vase was designed to contain the ordinary intoxicating beverage of the Aztec peoples, — the fermented sap of the century-plant (the *Agave Americana*), — the expression of this face would be singularly appropriate, and the association recall the bacchanalian figures moulded by ancient Roman artisans upon their drinking-cups of Samian ware. Enormous quantities of this national drink — the modern pulque, the ancient *octli* — are still consumed, and special trains upon the railway convey it in hogsheds and goat-skins to the capital city from the district where this clay object was discovered.

The story the ancient artist has sought to tell by every lineament of the face is evidently one of habitual and excessive drunkenness. The swollen eyeballs, covered by thick lids; the inane unsymmetric forehead, with a curious forked wrinkle on its weak side; the hanging full and flabby cheeks; the lips, tumid and uncontrolled, enclosing a meaningless mouth, — in all these we have a consistent story of continued vinous excess. This consistency is worthy of especial attention: not a feature or line in all the face fails to give forth the same mute evidence of complete abandonment to the poison. Finally, the artist, with a stroke of genius worthy of Hogarth, has caught the very spirit of besotted helplessness by sinking the entire right side of the face out of symmetry, thus proving, that, while possessing no knowledge of our modern notions of nervous centres and facial paralysis, the pre-Columbian sculptor had developed the capacity to place upon the human face the physiological evidences of a mind and body lost in the last stages of alcoholism.

No. 2 is also a fragment of some larger object, perhaps a vase. It was moulded, as was the case in the former instance, upon a soft prepared surface of clay, by means of a matrix, but it shows no evidence of retouching. It is the face, in relief, of an individual less deeply sunk in bacchanalian indulgence; but the expression is that of a drunkard, and not that of a person in the repose of sleep or nerveless in the relaxation of death. The lips are slightly apart, and there is breath between them. The eyes are closed, but the face is under control, and its texture is firmer than in the preceding figure. It is a work of less merit than No. 1, but the artist has succeeded in delineating drunkenness in every feature, and has maintained throughout the typical stolid expression of the aboriginal American races.

No. 3 represents a face moulded upon the leg of a terra-cotta vase. This portion of the clay vessels of Southern and Central America has often been seized upon by the ancient potter as a basis for elaboration. Sometimes it is wrought to represent the head of an animal, as the crocodile or fish; while among prehistoric pottery from the Chiriqui cemeteries, northward from Panama, nearly every carefully made vase has hollow legs. A ball of clay rattles loosely in this open space, and, through a narrow aperture, may be seen moving when the vessel is shaken. The Mexican vase-legs are in some localities quite abundant, because, like the "crescent ears" of the pots of the prehistoric Italian *terramare*, their solidity preserves them where the less firm portions of the vessels have crumbled. The exigencies of the case have confined the artist of this *basso-relievo* to a triangular surface, narrowing downward nearly to a point, and he has admirably adapted his work to the predetermined shape. On the foot of what may have been an ancient pulque jar we see here represented still another and a far more cheerful phase of intoxication. The individual has reached a state of mental excitement where he is "o'er all the ills of life victorious." He "accepts the good the gods provide" with child-like joy and abandon. In the elation of the moment he half closes his eyes, but at the same time, unlike the preceding inebriates, he finds companionship in the outer world by shrewdly keeping it in view. There is no flabbiness in his cheeks and lips: the former are bunched in a jolly grimace; the latter, drawn thinly over

his big teeth, broaden into a grin as successful as the narrowing margin of the vase-leg will permit. In short, we have before us the work of an aboriginal artist, who tells us successfully the story of a jolly reveller, who might be about to sing to his companions the chorus of "Willie brew'd a peck o' maut."

By turning this clay visage at various angles, it is found that the most advantageous view of the features is that from above. A large vase containing a liquid would in simple aboriginal habitations naturally be placed where it would rest below the level of the eye. Can it be possible the ancient artist wrought the model from which this vase-leg was moulded, conscious he was addressing eyes that would look from above upon his completed work?

With evidence before us such as that here detailed of the comparatively advanced culture in one direction of the old Mexican peoples, and of the capacity of some of their artists to deal successfully with complex questions in designing and modelling figures expressing conditions of the human mind, does it not seem probable that upon our southern border a rich field and many surprises await the patient scientific investigator? — a field that is all the more important to the anthropologist, because embedded in it is the history of a culture that may be autochthonous; and that is of all the more moment to us, because this culture grew through many centuries, subject to the developing forces of an environment in some important elements similar to that which is to-day modifying us and converting us into "Americans."

ROBERT H. LAMBORN.

STREET-RAILWAY MEN VISIT AN ELECTRIC RAILWAY.

ON Tuesday, Feb. 5, there was a gathering at Boston, Mass., of street-railway men of New England, who had come from all quarters of the six New England States. The object of the gathering was to inspect the electric branch of the West End Road at Boston, installed by the Sprague Electric Railway and Motor Company of New York. The party was met by Messrs. Blake & Sawyer, and the start was soon made from the Park Square end of the line in a number of electric cars which President Whitney of the West End Road had provided for the purpose. The cars were quickly filled by the street-railway men, and the departure made from Park Square in short order out to Boylston Street. The first stop was made at the power-station of the road, situated at Allston, where the visitors disembarked, and were shown the generating-station for the electricity used in operating the cars. On entering the main room, and passing by the two high-speed Arming-ton & Sims engines of 200 horse-power each, — one, though running, being so noiseless in its action that its motion passed almost unnoticed, — the four dynamos, of 80,000 watts capacity each, engaged the attention of the party. From each dynamo there are three leads passing under the floor to the switch-board, where connection is made by separate conductors to the underground conduit and overhead system. This switch-board and each regulator have for their bases an insulating compound to which they are fastened, and each regulator-shaft carries a gear; so that, by means of a rack which meshes into all four gears, the four dynamos may be regulated by one operation. Still higher on the wall are the safety fusible strips mounted on slate. At the top of the switch-board are placed four improved lightning-arresters resting on insulated brackets. These arresters consist of a large electro-magnet, which may be short-circuited in fine weather by a switch. From the terminal connected with the outside line there is a circuit with an alternative path to the ground, with the use of the usual break, an electro-magnet. To a lightning-current passing over the line, the large electro-magnet acts like a choking coil, and offers a large resistance; and the current, taking the alternative path, jumps over the air-space, when the electro-magnet, operating, breaks the circuit, thus extinguishing the arc. The power-station is lighted by a large number of electrolights, under control in groups of five, at a switch-board at one end of the building. The boiler-house has three 150-horse-power steel tubular boilers, with Jarvis setting, feed-water heater, injector, steam-pump, etc. The back wall of the power-house is built with a view to its extension in the rear, so that the capacity at the station can be

doubled, the position of the chimney being in the centre of the future station. Adjoining the power-station a new car-house has been erected, with capacity for twenty-six cars. The cars, when in this house, rest on skeleton tracks, under which the inspectors can walk, and, by aid of incandescent lamps with flexible connections, can examine and inspect the machinery of each car. After the party had fully examined the workings of the power-station, and listened to the explanations of its operation from the engineer in charge, they reboarded the electric cars, and were carried quickly out Beacon Street and Harvard Avenue to the terminus of the road at Oak Square, Brighton. To a great many in the party this trip was the first ever made on an electric railway, and the exclamations of surprise and delight were universal. On the return trip the cars were speeded to ten or twelve miles an hour in places, and much praise was bestowed upon the easy starting, which was prompt though without jar, the complete control over the car, and the ease of the car in rounding curves and in speeding. Each of the cars was brilliantly lighted by five incandescent lights of 16 candle-power each,—three inside the car, and one on each platform. These lamps had the municipal cut-out; and, when one

about 3,500 pounds, is 6 feet in height, and occupies a space 8 feet long by 2½ feet wide.

For tensile strength, the machine will test specimens up to 18 inches in length, 1¼ inches square, 1⅜ inches in diameter if round, and 2⅝ by 1 inch if flat, allowing for a 25-per-cent elongation in the longest specimens, and more for those of shorter length. For transverse strains, it will test specimens from 6 to 20 inches in length; and for compression, specimens up to 8 inches long and surfaces up to 6 inches in diameter. The pulling head has a movement of 23 inches. The machine has four different speeds for tensile and transverse tests, and two for compression, as follows: transverse and tensile, 4 inches per minute, 1 inch per minute, 1 inch in 3½ minutes, and 1 inch in 10 minutes; compression or reversing, 4 inches per minute, and 1 inch in 3½ minutes.

Power is applied by levers and friction-pulleys for starting, stopping, and reversing; and for changing the speeds, a hand-wheel and tumbling ball are used. In compression tests, and in tests of material not ductile, when the pressure is run up rapidly, there is an arrangement of friction-gears, similar to those of a hoisting-engine, which gives an extremely slow and steady motion to the

RIEHLÉ SCREW-POWER TESTING-MACHINE.

breaks, the increase of candle-power in the remainder calls the attention of the conductor, who inserts a new lamp. The visitors left Boston for their respective homes full of enthusiasm over the application of electricity to street-railways, and with a better knowledge of the advantages which electric power has for this purpose over any other power.

THE RIEHLÉ TESTING-MACHINE.

TESTING-MACHINES have become a necessary part of the equipment of all manufacturing establishments and constructive works, government and private, where the strength of materials must be accurately determined. Among the testing-machines now in use, those made by the firm of Riehle Brothers of Philadelphia stand prominent as examples of good workmanship, strength, accuracy, and convenience in use. The accompanying illustration shows one of these machines. It is a vertical screw-power machine for testing materials by tensile, transverse, and compression strains, and has a capacity of 60,000 pounds. Other machines made by the same firm range in capacity from 10,000 to 200,000 pounds. The levers on the machines of all capacities are adjusted to the United States Government standard.

The machine shown in the engraving is adapted for those whose requirements do not call for one of greater capacity. It weighs

screw, thus enabling the operator to make the test with ease and accuracy. The bearings are of hardened steel balls, which do away with much of the friction incident to this class of testing-machines.

THE FLEISCHMANN SYSTEM OF GARBAGE-DISPOSAL.

ONE of the systems of garbage-disposal which seems to be one of the best is that known as the Fleischmann, and is now in practical operation in Buffalo. In speaking of this system, the *Sanitary Inspector* says:—

“The Fleischmann system of garbage-extraction consists principally of two processes. The garbage, as it is hauled in, is shovelled through man-holes into driers below. There are two of these driers, each receiving at one charge 5,000 pounds of garbage. Each drier consists of a double-walled metallic cylinder, between the walls of which steam at a pressure of about eighty pounds is admitted. In the interior of each drier, a rake revolves, constantly stirring up the garbage. These rakes are composed of steam-pipes into which steam of the same pressure is admitted, but the steam is not admitted into the chamber which contains the garbage. The steam which arises by the drying of the garbage is drawn out of

the drier by means of a fan, so that a partial vacuum is constantly maintained in the drier; and this steam is carried into the lower part of a chamber, where, as it rises, it meets with a series of sprays or sheets of water which fall from overlapping shelves. In this way the steam which comes from the drier is condensed, and flows away as an inoffensive mill, having no more odor than the condensed water of an ordinary steam-radiator. In this process of drying, sixty per cent of the weight of the garbage is removed.

"The second stage of the operation consists in putting the dried garbage into an apparatus called an extractor, where the grease and oil which it contains is thoroughly removed by benzine used in an automatic way, so that it is used over and over again without loss. The present plant in Buffalo disposes of about 30,000 pounds of garbage daily. From this, about 1,800 pounds of grease is recovered; and the remainder of the dried and pulverized garbage, amounting to a daily average of about 12,000 pounds, is quite rich

SPRAGUE ELECTRIC ROADS AT READING AND WILMINGTON.

In this issue of our paper we present views of two recent electric roads, taken from photographs, — one in Pennsylvania, and the other in Delaware.

One of these represents one of the cars upon the Wilmington, Del., City Railway. This railway, which was installed by the Sprague Electric Railway and Motor Company of New York, has been in operation for about eight or nine months; and the president and the directors of this road have felt so very well pleased with its operation, that they have ordered an additional number of cars. The railroad is two miles long, using the regular Sprague overhead system of wiring, with small working conductor three-sixteenths of an inch in diameter, which, according to the Sprague system of electric railways, is the only wire suspended over the street.

SPRAGUE ELECTRIC ROAD AT WILMINGTON, DEL.

in ammonia, phosphates, and the other constituents which are valuable in fertilizers, and it is readily sold to the manufacturers of fertilizers. This dried product is screened, and what is removed is sorted out, and nearly all of it finds a market. The old rubber brings a good price; the rags are sold; the bones are valuable as a source of bone-meal; the waste tin, brass, and other fragments of metal, all readily sell; and only a small residuum, such as corn-cobs, pieces of crockery ware, etc., are used as filling. According to the showing of those who are peculiarly interested, and of the health authorities at Buffalo, a business of this kind pays a good percentage on investment, and an examination of the works must convince any person that a sanitary triumph has been achieved. Upon the first introduction of the garbage to this treatment, it is subjected to a temperature which of course immediately disinfects it, if any of it should be infectious; and from none of the processes through which the garbage is put is there the least odor which is suggestive of danger; and, though much benzine is used in the second stage of the treatment, no smell of it whatever is detected anywhere in the establishment during its use."

Our other view gives a representation of two electric cars on the East Reading and Black Bear Railway, passing each other upon a turnout. This road has recently been installed by the Sprague Electric Railway and Motor Company, and has been in operation only about two months. The road has been operating very successfully ever since its installation, and has been carrying a large number of passengers.

FOGS.

AT the anniversary meeting of the Royal Meteorological Society, held on the 16th of January, Dr. W. Marcet, president of the society, delivered an address on "Fogs," which he illustrated by a number of interesting lantern-slides. Fogs and clouds are one and the same thing. A cloud is a fog when entered into; and a fog seen from a distance, suspended in the air, becomes a cloud. After describing the various kinds of fog, — e.g., river, sea, Newfoundland, radiation, town, etc., fogs, — Dr. Marcet referred to London fogs. Dr. Tyndall has accounted for them by assuming each particle of

condensed vapor to be covered by coal-smoke. These fogs usually accompany a high barometer, and are frequently dry in their character.

It is a well-known fact that cold air on the tops of hills, being heavier than the air below, slides down the slopes; so that the lower parts of hillsides are actually colder than the plains at some distance from the hills. Now, London, in the Thames valley, is surrounded by hills, — to the north, Highgate, Hampstead, and Harrow; in a westerly direction, Putney and Wimbledon; and in a more southerly direction, Clapham and Sydenham. The air is colder on these hills than in London, with its millions of inhabitants, its coal-fires and factories: hence it is heavier, and will have a great tendency to slide down the hills towards the town and the river. Should the air in town be on the point of saturation, and the cold air from above saturated with vapor, it is obvious that the increased cold from above will produce a precipitation of moist-

working drawings made, but actual construction is required, and is made possible in extensive workshops, the equipment of which has cost over forty thousand dollars. In electricity, in addition to the instruments and appliances usually found in electrical laboratories, it possesses the most complete and accurately adjusted series of Sir William Thomson's electrical balances in this country; and there is a completely equipped testing-room for the purpose of calibrating and standardizing commercial instruments. Another important feature is the restriction placed upon the number of students admitted. The plan of the institute is to limit the attendance to such an extent as to realize the great benefits arising from small classes. Ample facilities will therefore be afforded to all who undertake its courses of study. Those who are contemplating preparation for either mechanical, civil, or electrical engineering, will do well to consult the catalogue of the Rose Polytechnic Institute.

TURNOUT ON THE SPRAGUE ELECTRIC ROAD AT READING, PENN.

ure, and it will come to pass that a fog is produced. If the hill-tops be not only colder than the air below, but enveloped in a fog, it stands to reason that the fog below will be all the denser, and especially in the neighborhood of water, such as the river Thames, and the ornamental waters in the parks.

THE ROSE POLYTECHNIC INSTITUTE.

THE Rose Polytechnic Institute is one of three or four schools in the United States which are especially devoted to the education of civil, mechanical, and electrical engineers. It owes its existence to the generosity of the late Chauncey Rose of Terre Haute, Ind., who bequeathed something more than half a million of dollars for its establishment and support. It is one of the youngest of the technological schools of the country, having been opened in the year 1883. One of the peculiar features of the institute is the thorough and extensive "shop-practice" of the students in mechanical engineering. Not only are machines designed, and

THE DERELICT AMERICAN SCHOONER "W. L. WHITE."

MR. EVERETT HAYDEN, meteorologist to the Hydrographic Office, has compiled the reports on the history of the derelict schooner "W. L. White," and the results of his investigation have been published on a supplement to the monthly "Pilot Chart," a portion of which is reproduced here. Besides showing the track of the "W. L. White," those of the derelict barks "Telemach" and "Vinuczo Perrotta" have been plotted on the map.

Mr. Hayden reports that a telegram dated Stornoway, Hebrides Islands, Scotland, Jan. 23, 1889, marks the termination of the remarkable cruise of this derelict vessel. Abandoned off Delaware Bay during the great blizzard, March 13, 1888, she has now completed her long and erratic transatlantic voyage, and lies stranded upon Hasker Island, one of the many little rocky islands of the Hebrides, in latitude 57° 42' north, longitude 7° 42' west. The track of this vessel, as plotted on the "Pilot Chart" from month to month during this long interval, has been of constantly increasing

interest, and a study of her track and the tracks of other derelicts plotted on the accompanying chart cannot fail to be valuable to every navigator of the North Atlantic, as illustrating the general course followed by these dangerous obstructions to navigation, and the irregularities to which this general course is subject. The fact may well be noted here that the tracks and latest reported positions of derelicts and wreckage on the high seas are shown on no other chart but the "Pilot Chart," and the danger to navigation caused by them is sufficiently indicated by the mere statement that the number recorded each month in the North Atlantic alone varies from twenty-five to as many as forty-five, every great ocean storm largely increasing the number. Therefore it is very desirable that masters of vessels should supply the Hydrographic Office with ex-

about by the varying winds, a constant menace to navigation along the greatest highway of ocean commerce in the world. During these six months alone she was reported by 36 vessels, three of which sighted her in a single day. In her cruise of ten months and ten days she traversed a distance of more than 5,000 miles, was reported 45 times, and how many more vessels passed dangerously near her at night and in thick weather it is impossible to even estimate.

The direction and force of the winds that helped to determine her track during this long voyage, as indicated by reports from hundreds of vessels in her vicinity at various times, were as follows: For a week after being abandoned, and in fact throughout March, with the exception of four days, she experienced north-westerly

TRACK OF THE DERELICT SCHOONER "W. L. WHITE."

act detailed descriptions of all such derelicts sighted, in order to make it possible to identify them with others previously reported.

The following brief summary of the leading features in the cruise of the "White" will be found of interest: She was a three-masted schooner, belonging to Mr. A. F. Ames of Rockland, Me., lumber-laden, and after being abandoned started off to the southward under the influence of the inshore current and the north-west gale, with masts and portions of her sails standing, and ensign set with union down. Upon reaching the Gulf Stream, she turned away to the eastward, and commenced her long cruise toward Europe, directly in the track of the thousands of vessels engaged in transatlantic commerce, drifting blindly about at the mercy of wind and current. The most remarkable feature is the zigzag track she followed in mid-ocean, between latitude 44° and 51° north, longitude 33° and 44° west, from the beginning of May till the end of October. Previous to this time she followed a course about east-north-east at an average rate of about 32 miles a day, and subsequently she moved east and north-east 1,260 in 84 days, an average of 15 miles a day; but during this long interval of six months she remained within this comparatively small area, drifted back and forth by the Gulf Stream and the Labrador current, and tossed

winds of varying force. Westerly winds continued during the first nine days of April, followed by five days of variable. From April 15 to 18 she encountered a strong westerly gale, followed by southerly winds, which prevailed the remainder of the month. Throughout May the winds were very variable, never more than two days in succession from the same direction. Moderate northerly gales were experienced on the 6th and 20th, and a fresh gale from the south-east on the 23d. Variable breezes continued throughout June, with westerly gales on the 24th and 30th. July opened with a moderate gale from the west, followed by south-westerly winds for a fortnight, hauling to west and north-west. Similar weather prevailed during August, with the exception of moderate gales from the eastward on the 6th, and from the westward on the 16th, 17th, and 22d. Generally westerly winds prevailed from Sept. 1 to 19, and easterly during the remainder of the month. During November the winds were westerly throughout, including several strong gales. Variable breezes were encountered during the first half of December, but during the remainder of the month the prevalent directions from south to west, with strong westerly gales from the 19th to the 25th. South-westerly winds prevailed from Jan. 1 up to the time she went ashore on Hasker Island.

The history of this derelict furnishes the strongest possible proof of the importance of this subject to masters of vessels, as well as of the cordial support which they have given to the Hydrographic Office in its efforts to collect and publish early and accurate information by means of which this danger to navigation may be diminished. The various commercial nations should unite in the effort to keep the seas clear of such obstructions, and it is a subject that may well be discussed by the forthcoming International Maritime Conference.

HEALTH MATTERS.

TYPHOID STATISTICS.—Professor Ruata of Perugia is authority for the statement that there are annually in Italy nearly 300,000 cases of typhoid-fever, of which number 27,000 prove fatal. One-third of the persons in Italy who reach the age of forty-five have the fever, and in some districts more than three per cent of the population die from this one cause.

ARSENIC IN FABRICS.—The *London Chemical News* states that Mr. A. W. Stokes has examined a hundred samples of imitation Indian muslins and cretonnes, and found that twenty-three per cent contained arsenic in appreciable quantities, the highest proportion 2.1 grains of white arsenic per square yard. The colors in which arsenic was principally present were the terra-cotta reds and the greenish-browns. Of the wall-papers submitted to Mr. Stokes by various manufacturers, ten per cent were found to contain arsenic. Thirty other articles of household use, such as plushes, velvets, carpets, mats, silks, etc., were examined, and in only one sample — a little flax mat of green color — was arsenic found.

BACTERIA IN THE GLACIERS.—Dr. Schmelt of Christiania (*Centralblatt für Bacteriologie*) has found vast colonies of bacteria in the ice of the Jerstedalsbrå glacier and in the streams fed by it. They appear under the form of rods, and resemble the *Bacillus fluorescens liquefaciens*. During their period of growth these bacteria emit a fluorescent material. They multiply with great rapidity during periods of thaw.

A NEW DEODORANT.—Bromine has for a long time been recognized as being valuable in the treatment of gangrene and foul-smelling ulcers; but until recently its merits as an effectual and cheap deodorant have not been appreciated, according to the *New York Medical Journal*. It was brought into prominence a few months ago by Mr. Martin, the chemist of the health department of this city, who suggested its use upon the earth thrown up in laying the electric subways. As it is a by-product obtained in the manufacture of salt, and is not used extensively in the arts, it is sold at a very reasonable price, — about seventy cents per pound. It has the property of precipitating the hydrocarbons of illuminating-gas, and thus can be used to deodorize the earth exposed in excavations in the vicinity of gas-mains. More valuable than this is its effect upon decomposing organic bodies, which it renders completely inoffensive. This property renders it particularly valuable for use in stables, privy-vaults, urinals, cesspools, or in any place which may contain foul-smelling organic matters. It is soluble in about thirty-three parts of water; but a solution of this strength is not advisable, as there is a constant escape from it of the vapor of bromine, which is very irritating to the eyes and air-passages, and which may even attack wood and metals. For ordinary purposes it is used in solutions containing one part by weight to about eight hundred of water. In this strength it may be used freely without its affecting any thing which it may touch. A few gallons used daily will remove all ammoniacal odors from stables, or a few quarts will thoroughly deodorize the entire plumbing system of an ordinary house. It also might be used with advantage upon ordinary house-garbage, which usually becomes offensive so speedily in warm weather. There would appear to be scarcely any limit to its usefulness in this branch of sanitary science; and it will, as soon as its merits are better known, undoubtedly be adopted universally as a substitute for the deodorants now in use, which usually act by substituting one unpleasant odor for another. The only drawback in its use lies in the fact that the undiluted bromine is strongly corrosive; and, if it touches the skin, causes a painful

burn. Where it is used in large quantities, this can be obviated by opening the bottle, or, what is simpler, breaking it, under water. As its use becomes more extended, it will undoubtedly be put up in pearls or tubes containing only as much as would be needed at one time in the average household.

TRANSMISSION OF DIPHThERIA.—Dr. De la Roche believes that diphtheria can be transmitted from animals to man. He has had under his care two women suffering from diphtheria, which he thinks he has traced to the contamination of drinking-water from a cistern by the excrement of pigeons, which had been washed down by the rain from the roof on which these birds had perched. Admitting the possibility of the transmission of diphtheria in this manner, the means of combating it are simple. In places where spring-water and well-water are not available, or where the supply consists of rain-water collected in cisterns, it is well to limit pigeon-breeding, and to construct dove-cotes as far away as possible from dwelling-houses. As to the construction of cisterns, they should be built according to the rules of public hygiene laid down by Gania in his work entitled "Utilité des Cisternes."

MALARIA.—Dr. Henry B. Baker, the well-known sanitarian, contributed a paper, at the last meeting of the American Medical Association, on "Malaria, and the Causation of Periodic Fever." After an able discussion of the subject, he sums up as follows: "So far as evidence is yet presented, it seems to be proved, then, that (1) intermittent fever is proportional, directly or inversely, to the average daily range of atmospheric temperature; (2) the controlling cause of intermittent fever is exposure to insidious changes, or changes to which one is unaccustomed, in the atmospheric temperature; (3) in the mechanism of the causation of intermittent fever, the chief factor is the delay in the re-action from exposure to cool air (this delay, extending to a time when greater heat-loss should occur, results in the abnormal accumulation of heat in the interior of the body, and in disturbed nervous action, — the chill), and the final re-action is excessive because of the accumulation of heat, and sometimes because it occurs at the warmest part of the day; (4) the fever is the excessive re-action from the insidious influence of the exposure to cool air, and it is periodical because of the periodicity of nervous action, and because the exposure and the consequent chill are periodical, owing to the nightly absence of the warmth from the sun; (5) residence in valleys, or on low lands through which or upon which cold air flows at night, and thus causes insidious changes in the atmospheric temperature, favors intermittent fever; (6) in our climate, those measures, such as drainage, which enable the soil to retain warmth during the night, and thus reduce the daily range of temperature immediately over such soil, tend to decrease intermittent fever among residents thereon; (7) in the cure and prophylaxis of intermittent fever, those remedies are useful which lessen torpidity, and tend to increase the power of the body to re-act promptly to insidious changes in atmospheric temperature; (8) the slowness of the pulse, and other indications of torpidity, associated with retention of bile or with certain disturbances of the functions of the liver, are well known; but, so far as known to the writer, these conditions have not heretofore been considered as causative of the fever in the manner herein suggested.

SCIENTIFIC NEWS IN WASHINGTON.

Rock-Gas and Related Bitumens. — A Diagram of the World's War-Vessels. — The Eastern Cherokees. — Some Habits of Koreans.

Rock-Gas and Related Bitumens.

IN a communication (the second on the list) presented before the Philosophical Society on Feb. 2, Mr. W. J. McGee pointed out, that, *pari passu* with the industrial development accompanying the utilization of rock-gas, geologic science has made an unparalleled stride within a few months. When exploitation for gas began in Ohio in 1886, the geologist found himself utterly unable either to guide the efforts of the prospector or to predict the results of his work; yet within the ensuing two years the laws governing the accumulation and distribution of gas and oil have been so fully developed that the rock-gas problem to day claims a solution as satisfactory as

that of the well-known artesian-water problem, and the geologist predicts the success or failure of a prospect bore for gas or oil about as readily and reliably as he predicts artesian water or coal. The solution of the problem of rock-gas and petroleum marks an era in science no less than in industry. Mr. McGee discussed also the origin and distribution of gas, petroleum, and allied bitumens, showing that they are distributed throughout the various countries and geologic formations of the globe; that, other things equal, they are most abundant in the newer formations; that, other things equal, they are lighter in newer than in older formations; that the commercially available supplies of oil and gas are accumulated in natural reservoirs formed by flexures of the rocky strata into domes and anticlinals; and that in the American fields, at least, rock-gas, petroleum, and the heavier bitumens are simple products of natural processes of decomposition of the organic matter contained in sediments, their weight and other attributes depending upon the conditions under which decomposition took place. In conclusion, he pointed out that at the present rate of consumption the coal-fields of the earth will be exhausted within a few centuries, when it will become necessary to utilize, more completely than has yet been done, the much more abundant supplies of carbon compounds disseminated throughout the rocks of the earth in the form of bitumen. Rock-gas and related bitumens are indeed destined to form the fuels and illuminants of the future.

A Diagram of the World's War-Vessels.

Lieut. R. P. Rodgers, chief of the intelligence bureau of the Navy Department, has arranged in his room a curious and important map. It is a large map of the world on Mercator's projection, and on its surface are pinned colored tags showing the present position of all the war-vessels of the world. British vessels are represented by red tags, French by light blue, German by purple, American by dark blue, etc., and the positions of them are daily re-adjusted so as to conform to the latest advices. By this pictorial arrangement the secretary can in a moment sweep the seas, and ascertain exactly the whereabouts and strength of the naval power of the world.

Of the ships indicated in commission on the map, about one hundred and fifty belong to Great Britain and one hundred to France, while Germany and the United States have not more than forty each. Italian ships are mostly in the Mediterranean; Spanish ships, chiefly in the West Indies and at home. Germany has three warships at Samoa; the United States has one, and two more on the way, in the aggregate superior to the German contingent. China has a dozen or twenty ships, all on her own coast. She is not aggressive. In Central America we are outnumbered in a way to suggest that the Monroe doctrine is not to be enforced at once. We have at the Isthmus of Darien one pretty poor ship on the east side, none on the west side. France has one on each side, and Great Britain has three on each side. We have four vessels on the West African coast, and half a dozen in the seas of the Orient.

The Eastern Cherokees.

Mr. James Mooney of the Bureau of Ethnology, who has been for several years studying the Cherokees, is making some interesting reports of their condition and customs. It may not be generally known, he says, that the Cherokees, whose expulsion from Georgia and the contiguous States in 1838 was one of the most flagrant violations of treaty rights ever perpetrated by the United States Government, have not entirely abandoned their ancient country. On the contrary, a portion of the tribe, officially known as the "Eastern Band of Cherokees," still keeps up an organization in North Carolina, with its council, chiefs, and medicine-men, and numbers in all about two thousand souls, of whom about fifteen hundred are mainly full-bloods, speaking only their native language, while the remainder are more white than Indian. In addition to these, the official roster includes several hundred others who claim Cherokee rights, — to wit, a share in the tribal lands and educational privileges, — but the keenest observer could not distinguish them from any other white men; and their Indian blood, which in many cases is an extremely doubtful quantity, and denied by the Cherokees themselves, is about as dilute as that of the modern descendants of Pocahontas. Excluding these pseudo claimants, it will thus be seen, by reference to the report of the Indian commissioner, that

we still have in North Carolina a body of Indians about as numerous as the Arapahoes or Winnebagoes in the West, and far outnumbering such noted tribes as the Pawnees, Omahas, Osages, Comanches, and Nez Percés.

These Cherokees are chiefly in Swain, Jackson, and Graham Counties, and own altogether eighty-eight thousand acres. The reservation proper lies principally in Swain County, and contains one hundred and fourteen square miles, occupied by about twelve hundred souls, very few of whom can speak English. Their principal settlement is Elawāti ("paint clay"), known to the whites as Yellow Hill or Cherokee. Here are the council-house, the chief's residence, and the government training-school, containing nearly a hundred children under the efficient instruction of teachers appointed by the Quakers, under a contract with the government. There are five other day-schools supported by the interest on their *pro rata* share of the fund appropriated for the removal of the Cherokees in 1836. Aside from this, the band receives no aid from the government, the Supreme Court having decided that they are not entitled to participate in the benefits arising from any former treaties with the Cherokees, so long as they refuse to join the body of the tribe in the Indian Territory, — a proposition to which they are bitterly opposed. Their legal status is a peculiar one. Although living on a reservation, under care of an agent, and holding their lands in common, they are treated rather as intractable children, and deprived of the privileges accorded the rest of the tribe; while, on the other hand, they have the rights of citizenship, and vote at all local and general elections. In politics they are Republicans almost to a man, as they consider the success of their schools due to that party.

These Cherokees are the descendants of the few individuals who were allowed to remain under the treaty of removal in 1835, and of the larger number who fled to the mountains, and thus eluded the soldiers who were sent out under Gen. Scott to collect the Indians for removal to the West. Many of the older ones still remember with bitterness the events of this period. These Indians may fairly be called warriors, as three hundred of them served in the Confederate army during the late war, while quite a number also fought on the Union side. The former were a part of the Thomas Legion, occupied chiefly in East Tennessee. They are now quiet, law-abiding citizens, cultivating their small farms, and gathering chestnuts and ginseng in the mountains, to trade for cloth and coffee at the neighboring villages. A few are fairly prosperous, but the majority are in a condition of abject poverty. Isolated in the heart of the mountains, neglected by the general government, and deprived even of schools until within a few years ago, they are fully two-generations behind their more fortunate brethren in the West, and still keep up their old dances, ball plays, and conjuring practices, although many of them are professing Christians. Their present chief, N. J. Smith, known to his tribe as Tsalatibi, is an honorable and intelligent gentleman, of three-fourths Cherokee blood, speaking both languages fluently, and thoroughly devoted to the interests of his people. Through his efforts and the influence of the schools, the old Indian life is gradually giving place to the newer civilization.

Some Habits of Koreans.

On Saturday afternoon, Feb. 2, Mrs. E. R. Scidmore read a paper on the home-life of the Koreans, among whom she visited in 1887 as a guest of Judge Denny, the foreign adviser to the king. She said the Koreans are in most things poor copies of the Chinese. Their dress is the same as that worn by the Chinese before the Manchu conquest, which made the pigtail obligatory as a sign of submission. Wisps of straw and bits of cloth, says Mrs. Scidmore, hang at the doorways to delude the Devil and keep off evil spirits; and these are the only signs of worship seen about Seoul. They have the worship of ancestors, as the Chinese; and a trace of the old dragon-worship must order their toleration of snakes, as it is impossible to get a Korean servant to kill the snakes that drop from the mud roof and slip out of the flues of the kaugs that warm the floors of the houses.

Until the arrival of the American physicians, the king and queen had an army of necromancers and wizards in attendance upon them, and a form of shamanism was practised upon the sick. They were consulted as well in matters of state policy.

The strict seclusion of the women is relaxed on one day in June, when women may go anywhere with uncovered faces. The homes of the foreign residents in Seoul are visited then by thousands of curious women.

If a man walks over all the foot-bridges of the city on the middle day of January, he is supposed to secure good health for the year.

The city gates are closed and locked from dark until dawn, and it is death to the guardsman who opens them to admit any one. Generations of belated and wall-scaling Koreans have worn a staircase of crevices in the wall by which they mount to the gate tower; or the guardsmen will haul them up by a rope, there being a regular tariff of charges for the use of ropes, and the mandarins getting their regular percentage of the fees.

The manufactures of to-day are very crude and wholly inartistic. Peddlers of tin bring pieces of iron damascened with silver, that at once prove the Persian influence of the old arts by the decorative forms. Korean ambassadors are supposed to have met the Persians at the Peking Court in the time of Gingshis and Khublai Khan.

ETHNOLOGY.

Mound-Builders and Indians.

IN a recent number of the *Ohio Archeological and Historical Quarterly*, Mr. Gerard Fowke attempts to disprove "popular errors in regard to mound-builders." The author shares the view of Professor Cyrus Thomas, that the mound-builders were Indians, and that no great antiquity must be claimed for their works. The principal points adduced by the supporters of the theory of the existence of an ancient high state of culture and of a dense population are taken up one by one and discussed. Thus he reduces the opinion regarding the high character of the works of the mound-builders to its proper level. One of the important points to be decided, in an estimate of this ancient race, is the question regarding the density of population. The same reasons which were claimed for an ancient dense habitation of Arctic America have been considered as proof in the case of the mound-builders. It is said that numerous ruins on a limited area indicate a great number of inhabitants; but, as no proof can be given that they have been inhabited simultaneously, it is quite possible, that, notwithstanding their great number, the population was very sparse. It seems to us that the author's doubts as to a considerable antiquity of some of these ancient monuments are not well founded; but his criticism of the exaggerated views regarding the works and civilization of this ancient race is timely, and will help to the formation of a juster appreciation of the real significance of these works.

THE JADE QUESTION.—F. W. Clarke and G. P. Merrill have made an examination of a series of jade implements from the collections of the United States National Museum. The results of this investigation, which were published in the "Proceedings of the United States National Museum," are in favor of the theory that the occurrence of implements made of similar varieties of jadeites and nephrites in widely separated countries must not be considered proof of a common source of the material. The authors, whose arguments are based on very exhaustive microscopical and chemical investigations, believe that it is hardly practicable to distinguish, by means of thin sections and the microscope, between nephrites from various sources. "The presence or absence of enclosures of diopside, magnetite, or ferruginous oxides; the condition of these oxides, whether as ferric or ferrous; the varying tufted, bent, confused fibrous and even granular condition of the constituent parts,—are all, together with the color-variations and other structural peculiarities, matters of too slight import to be of weight from a petrographic standpoint. If, as seems possible, the majority of the nephrites are of secondary origin, why may we not expect to find all, or at least a great variety, of the structures described in the same or closely adjacent rock-masses? Chemical analyses on samples from near-lying, or even the same, localities are found often to vary as greatly as those from localities widely separated. Why may we not expect the same structural variations, when once they are carefully looked for? To our own minds, sufficient assurances that the widely scattered jadeite and nephrite objects were derived from many independent sources, and possess no value whatever in the work of tracing the migration and inter-communi-

cation of races, lie in the fact that these substances are comparatively common constituents of metamorphic rocks, and hence liable to be found anywhere where these rocks occur. Their presence is as meaningless as would be the finding of a piece of graphite. The natives required a hard, tough substance capable of receiving and retaining a sharp edge and polish, and took it wherever it was to be found."

SIGNALLING AMONG PRIMITIVE PEOPLES.—As is well known, the Indians of our continent use rising smoke to give signals to distant friends. A small fire is started, and, as soon as it burns fairly well, grass and leaves are heaped on top of it. Thus a large column of steam and smoke rises. By covering the fire with a blanket, the rising of the smoke is interrupted at regular intervals, and the successive clouds are used for conveying messages. Recently R. Andree has compiled notes on the use of signals by primitive people, and finds that they are well-nigh in universal use. Recently attention has been called to the elaborate system of drum signals used by the Kamerun negroes, by means of which long messages are sent from village to village. While it was supposed that this remarkable system of communication was confined to a limited region, explorations in the Kongo basin have shown that it prevails throughout Central Africa. The Bakuba use large wooden drums, on which different tones are produced by two drum-sticks. Sometimes the natives "converse" in this way for hours; and from the energy displayed by the drummers, and the rapidity of the successive blows, it seemed that the conversation was very animated. The Galla south of Abyssinia have drums stationed at certain points of the roads leading to neighboring states. Special watchmen are appointed who have to beat the drum on the approach of enemies. Cecchi, who observed this custom, designates it as a "system of telegraphs." The same use of drums is found in New Guinea. From the rhythm and rapidity of the blows, the natives know at once whether an attack, a death, or a festival is announced. The same tribes use columns of smoke or (at night) fires to convey messages to distant friends. The latter are also used in Australia. Columns of smoke of different forms are used for signals by the inhabitants of Cape York and the neighboring island. In Victoria hollow trees are filled with fresh leaves, which are lighted. The signals thus made are understood by their friends. In eastern Australia the movements of a traveller were made known by columns of smoke, and so was the discovery of a whale in Portland Bay. These notes, which might be increased considerably, show the general existence of methods of communication over long distances,—the art of telegraphing in its first stages of development.

NOTES AND NEWS.

RECENTLY much light has been thrown upon the phenomena of glaciation in Greenland. Dr. F. Nansen's daring trip across the inland ice will clear up important questions regarding the meteorological conditions of the interior and the maximum height of land. In the past year Mr. Ch. Rabot has examined the ice phenomena of the west coast, and arrived at the conclusion that the glaciers of Lapland must be considered inland ice in miniature. He is of the opinion that the latter must be considered vestiges of the glacial period in Scandinavia, which have remained to the present day in consequence of particular circumstances. He also observed that the great glacier of Jacobstown has advanced almost two miles since the year 1878.

—Mrs. Amélie Rives-Chanler has offered a prize of \$100 for the best American essay on child-labor. The money has been placed in the hands of Professor Richard T. Ely of Baltimore, secretary of the American Economic Association. The essay must not exceed 55,000 words, and must be in Professor Ely's hands not later than Dec. 2, 1889.

—The Royal Society of Palermo has decorated Professor P. T. Austen of Rutgers College with a gold order, in recognition of his scientific work.

—The following meetings will be held in Paris in August, 1889: viz., Congress of Geography and Ethnology, from Aug. 5 to Aug. 12; Association Française, Aug. 8 to Aug. 15; Congrès d'Anthropologie, Aug. 19 to Aug. 26.

THE CHARTER of the Maritime Canal Company of Nicaragua has at last been granted by Congress. The plans for this great enterprise have been laid out so carefully, and the difficulties and advantages of the various routes have been considered so conscientiously, that the attempts at obstructing the passage of the bill were in no way justified. The feeling of the House on this subject was well expressed by the applause with which the passage of this important bill was greeted. The resistance offered on the alleged ground that the United States might be obliged to take up the work of the company was the more absurd, as the concession by the State of Nicaragua expressly states that no government except those of Central American States is allowed to hold shares in the company, and that the concession cannot be ceded to the government of any nation. The work will certainly be pushed with as much vigor as the surveys have been carried on, and we do not doubt that the canal will be completed in a very few years. The company has fulfilled the requirements of its concession by the State of Nicaragua, referring to the commencement and completion of the final surveys, and for the organization of an executive company; and the work of construction will also be begun in due time. While the prospects of the construction of the Nicaragua Canal are hopeful in every respect, the formation of the new Panama Canal Company has proved a failure. It will largely depend upon political

events in France, whether the work can be carried on or not; but recent events have proved that the confidence of private capital in M. de Lesseps' enterprise is not sufficient to enable him to carry on the enormous work that has to be accomplished towards the completion of his lock canal. It remains to be seen whether the government of France will be able to withstand the pressure exerted upon it in taking up the work. The long delays and evident difficulty of the route cannot but be of advantage to the Nicaragua Company, which will be able to absorb a large proportion of the working force kept idle at Panama.

THE CAUSE OF PROGRESS AND REFORM in New York City schools received a great impetus last Wednesday, when the Public Education Society submitted, through its committee, a memorial to the Board of Education on the state of the schools. This memorial was received and referred without comment to the committee on reform, to whose own report we have recently made reference in these columns. The memorial opens with the statement that the Public Education Society believes the New York City schools, as at present organized and conducted, to be deficient in respect to accommodations provided, in respect to courses and methods of instruction, and in respect to administration. In support of its belief, the society submits a number of facts. From the perusal of these, we learn that during the past year there were 150,312 pupils registered in all the schools. Of this number, 55,018 were registered in the grammar schools, and 95,294 in the primary schools. For the grammar schools there were provided 1,575 teachers, and for the primary schools 1,741 teachers. From this the society goes on to show, that, although the conditions in the grammar departments are bad enough, those in the primary schools and departments are infinitely worse. The primary schools or departments are invariably placed on the lowest floor of the school-building, where there is the least light, the greatest amount of dampness, and the greatest amount of exposure to foul and unpleasant or unhealthy surroundings. It seems that in the lowest primary grade the classes average in size 87 pupils to every teacher. This fact is in itself astounding, and a sufficient indictment of the entire system. It must be borne in mind that these children are the youngest and most impressionable in the schools, and that many of them are not six years of age. In the next lowest primary grade the classes average 58 pupils to the teacher; and in the grade above that, 56 pupils to the teacher.

It is then shown, that although the regulations of the Board of Education call for very meagre allowances of floor space and cubic air space per pupil, yet the law is violated in hundreds of instances. A list of 185 school-rooms is given in which members of the society, by actual inspection, have found the law to be violated to an alarming extent. For instance: school-rooms meant to hold 52 pupils are found to have 75 in average attendance, and one room which was meant to hold only 44 had 73 little children crowded into it daily. In spite of this overcrowding, 3,873 pupils were denied admission to the schools during the first week in September, 1888. The lack of play-grounds is adverted to, and an admirable suggestion made that the authorities should follow the example of London, and place the play-grounds on the roofs of the school-buildings in cases where the value of real estate does not permit the purchase of ground adjoining the school-houses. In illustrating the deficiency of the courses and methods of instruction, the memorial is very forcible. It shows, that, while the school-children in New York City are hard-worked and the curriculum overcrowded, the progress is not nearly so great as it is in the elementary schools of a number of European countries. It is chargeable, too, against the New York City system, that the course of study is arranged for the sole benefit of those who pursue it throughout, whereas not less than 60,000 children annually leave the public schools before they reach the age of twelve years. These children have had no

thorough or complete training in any one subject, they have merely made a certain amount of progress in a variety of branches; and in a large majority of cases this incomplete and disjointed instruction is all the education that these children will ever receive. The memorial protests against thus subordinating the primary-school course to the grammar-school course and that which succeeds it. The methods of examination and marking are unhesitatingly condemned, and ample evidence is quoted to sustain the charges.

The awkward and incongruous nature of school-administration seems to be very apparent. The Board of Education, the school inspectors, the school trustees, and the assistant superintendents have various and conflicting duties. It seems impossible to reach any sound basis for progress until these methods of administration are simplified and their efficiency increased. Then the improvements necessary in the course of study may naturally follow. The Public Education Society recognizes this fact, and therefore closes the memorial with the suggestion that a special commission, which shall include some members of recognized reputation and authority in matters of education, be appointed to investigate the conditions as they now exist in New York City, and to codify and simplify the school law. We earnestly hope that this proposition of the society will meet the approval of the Board of Education, and that the necessary steps will be taken to carry it into effect. The committee on reform, to which the memorial was referred, is certainly in sympathy with the Public Education Society. It now remains to so press this subject upon the attention of the majority of the Board of Education that the recommendations of the memorial will be adopted.

THE STANLEY EXPEDITION.

THE *Mouvement géographique* prints the various letters which have reached Brussels from Stanley Falls, and it is only now possible to understand somewhat clearly the course of Stanley's expedition. It will be remembered that Stanley sent a letter to Tippo-Tip. About the end of last year Lieut. Alfred Baert, secretary of Tippo-Tip at Stanley Falls Station, was obliged, on account of severe illness, to leave his post. His reports supplement Stanley's letter.

Stanley says that the route from Yambuya on the Aruvimi to Emin's province is excellent, and that provisions can be readily obtained. He does not say how long it took to accomplish the distance from Yambuya to Lake Albert Nyanza, but he states that the way back was accomplished in less than three months.

On the Albert Nyanza he met Emin, who, according to his last letters, was expecting to meet him there. The telegram of Dec. 23 stated that Stanley had left Emin near the Victoria. This fact appeared surprising, as it implied that Emin had left his province. This report appears to be due to a misunderstanding, Stanley saying in his letter that he had left Emin on the Nyanza, referring evidently to the Albert Nyanza, not to the Victoria Nyanza. After having organized a caravan of one hundred and thirty Wangnana, sixty-six men lent by Emin, and three soldiers, Stanley and his four white companions—Nelson, Stairs, Parke, and Monterey Jephson—left Emin on May 27, and returned to Yambuya by the way they had come, in order to look after the rear guard left there in charge of Major Barttelot, who was accompanied by Jamieson, Bonny, Rose Troup, and Ward. On Aug. 17, Stanley, who commanded the vanguard, arrived at Banalya. This place, which has so much puzzled geographers, is situated in Urenia, and is the same place at which Bonny, the commander of the vanguard of Barttelot, encamped on the bank of the Aruvimi. It is situated about fourteen days above Yambuya, and seven or eight days north-east of Stanley Falls. At Banalya, Barttelot was murdered by one of his men about a month before Stanley's arrival. When Stanley arrived, Bonny was still encamped there with part of the men furnished to Barttelot by Tippo-Tip.

On the following day Stanley wrote to the commissioner at Stanley Falls that he intended to stay there for ten days, and asked him to accompany him to Wadelai. Tippo-Tip declined this offer;

and Stanley, after having sent another letter to Stanley Falls, started on his way back to the Albert Nyanza.

Mr. A. J. Wauters, the editor of the *Mouvement géographique*, adds, "It will undoubtedly be found remarkable that Stanley, after an absence of more than a year in the fastnesses of Central Africa, without any news from Europe since May, 1887, did not push on to the Falls Station, where he was sure to meet Europeans and to find news. But he undoubtedly wished to avoid being asked questions regarding his discoveries, and regarding Emin and his projects, and therefore he left Banalya as rapidly as possible."

He re-enforced his caravan by one hundred carriers of Barttelot, his caravan now numbering two hundred and ninety-six men: Mr. Bonny, the only white man of Barttelot's rear guard, still on the Aruvimi, joined the expedition, which started eastward in the beginning of September. If he returned as rapidly as he came from the Albert Nyanza, he must have arrived there about the end of November.

These reports show that Osman Digma's letter, pretending that the Mahdi had captured a European at Lado on Oct. 10, cannot refer to Stanley or to Dr. Parke. They also dispose of the theory that the "white pacha" who was reported from the Bahr-el-Gazal region was Stanley; and Lieut. van Gele's hypothesis that these rumors referred to his expedition up the Obangi gains some probability.

Stanley's correspondence addressed to Europe reached Stanley Falls on Sept. 14. As Lieut. Baert left the station by canoe, he did not take these important documents along, which were kept back by Lieut. Haneuse. Lieut. Baert arrived at Bangala early in November, where he met the steamer "Stanley," which conveyed a number of men to the Aruvimi, where a station of the Belgian Company was founded at that time. He reached Leopoldville on board this steamer on Nov. 30. Stanley's letters are expected in Europe about a month or two hence.

THE TOPOGRAPHICAL SURVEY OF RHODE ISLAND.

THE endeavors of the Providence Franklin Society to arouse interest in a topographical survey of the State of Rhode Island have found a ready response in the Legislature of that State, and we learn with great satisfaction that the field-work for a map of Rhode Island has been completed. The work has been carried out by the United States Geological Survey on a plan similar to that of Massachusetts, the State and the United States Geological Survey sharing the expense equally. The State of Rhode Island falls upon fifteen different sheets of the great "Atlas of the United States," only five of which are wholly within the State. The total cost of the work to the State of Rhode Island will be five thousand dollars. The commissioners, David W. Hoyt, John W. Ellis, and Winslow Upton, to whose endeavors we owe the taking-up of this important work, conclude their report with some important considerations and suggestions. "The State," so they say, "will obtain a map similar to that which was contemplated in the plan of 1876, on a somewhat smaller scale, at one-quarter the estimated expense to the State. While this topographical survey is complete in itself, for all that it professes to do, it does not undertake to determine the boundary-lines of towns. This has been done in Massachusetts, as supplemental to the topographical survey, under an additional appropriation. Neither does this survey undertake to erect exact and permanent bench-marks from which levels may be reckoned.

"The commissioners desire to call the attention of the General Assembly to the fact that no provision has been made, either by the United States or by this State, for the publication and distribution of this map. To be of service, some arrangement should be made whereby it can be supplied, at a moderate expense, to the citizens of the State, as soon as practicable after all the plates have been received.

"In the atlas published by New Jersey, whose survey has been completed in co-operation with the United States Geological Survey, seventeen sheets are made to cover the entire State. The sheets overlap each other to some extent, and are so arranged as to be of the greatest value for local purposes. Each sheet includes more than three times the surface of a sheet of the United States Ge-

ological Survey, but is constructed on the same scale. These maps are sold at the cost of paper and printing. A somewhat similar plan, requiring five to eight sheets, might perhaps be adopted with advantage in this State. Each city, town, and village should, so far as possible, be found entire upon some one sheet; but to secure this, the original plates must be combined and re-arranged, and adjoining sheets must be made to include the same territory to some extent.

"It is desirable that a wall-map of the whole State should be published, in addition to the atlas form just mentioned. A map about $3\frac{1}{2}$ feet by 5 feet in size would include the whole State, with Block Island in its true position. This could be easily arranged, provided the State authorize some arrangement for such publication."

The three States of Massachusetts, Rhode Island, and New Jersey have thus been the first to secure, by a wise co-operation with the United States Geological Survey, good topographical maps of their whole territories. It is one of the most important objects of this institution to make a good map of the United States, without the aid of which no geological work can be carried on satisfactorily. On account of the wide extent of our country, this enterprise is enormous, and requires a long time for its accomplishment. By the co-operation of States the work which is of the greatest importance can be accelerated, and it is to be hoped that other States will follow the example set by three of their number, the good results of which may be seen from the map of New Jersey, so far the only one published.

THE GREAT STORM OF MARCH, 1888.

It is only after a long period has elapsed that it is possible to describe accurately the meteorological conditions that prevailed at a certain time over a large area, particularly over extensive parts of the ocean; therefore it has not been possible until recently to write the history of the great blizzard that visited the Atlantic States from March 11 to 14, 1888. Lieut. Everett Hayden, who is in charge of the Division of Marine Meteorology of the Bureau of Navigation, has undertaken this work, and presented the results of his interesting study in the fifth of the "Nautical Monographs." The book, which contains the original observations made by masters of vessels in full, is bound in leather to enable it to stand the rough handling incident to use aboard ship, where books in ordinary cloth bindings are quickly ruined. The list of observations shows how valuable is the aid that voluntary observers aboard ships give to the work of the Hydrographic Office. The history of this memorable storm is based almost exclusively on their reports: therefore the endeavors of the Hydrographic Office to enlist as great a number of masters as possible as voluntary observers, and to increase the general interest in marine meteorology among mariners, deserve the greatest possible success. It is well known how much more readily a man will undertake such observations if he knows that they are actually used, than if he believes that they are buried among a vast amount of material: therefore the plan of publishing a monograph of a remarkable gale, with a complete list of observations appended, will, aside from its scientific value, instigate many a mariner to continue or to take up meteorological observations at sea.

Lieut. Hayden represents the meteorological conditions over the Atlantic coast and the adjoining parts of the ocean in four charts, showing lines of equal pressure and of equal temperature. In order to make the maps clearer, temperatures above freezing are represented in pink; those below freezing, in blue; the depth of shade increasing with the departure from this point. In this way the advance of the cold wave from the interior towards the seacoast is shown with admirable clearness, and the meteorological events are easily understood. In the text, the history of the storm is traced from March 11, 7 A.M., when a long trough of low barometer, extending from the west coast of Florida up past the eastern shore of Lake Huron, and far northward, was advancing eastward, causing strong north-westerly winds on its western side. At 10 P.M. this line had advanced eastward as far as the 74th meridian. The cold north-westerly gale, as it is now sweeping over the great warm ocean-current, carrying air at a temperature below the freezing-point over water above 75°F. , is rapidly gaining strength, and be-

comes a fierce hurricane. An area of high barometer, which was at Newfoundland the previous day, is slowing down, blocking the advance of the rapidly increasing storm, and about to hold the centre of the line in check to the westward of Nantucket for days, while a terrific north-west gale plays havoc along the coast from Montauk Point to Hatteras, and until the right flank of the line has swung around to the eastward far enough to cut off the supply of warm, moist air pouring in from the north-east. The special value of Lieut. Hayden's description lies in his clear treatment of the influence of the warm, moist Atlantic air upon the development of the storm. He sums up the observations on this argument as follows: "The storm has called attention anew to the sudden deepening of depressions upon reaching the coast, and the corresponding increase of energy to be expected, — a lesson that should be borne in mind by every navigator leaving port with a falling barometer, and other signs of a storm. It has reminded us of the vitally important influence of the Gulf Stream in causing such increase of energy, and to the necessity of closely watching this great warm ocean-current, and noting any abnormal conditions of volume, velocity, temperature, and position; especially so during the spring and autumn months, — the periods of most rapid change in the conditions of oceanic and atmospheric circulation. The storm has established in most unmistakable terms the importance, not only to our extensive shipping interests, but to the people of all our great seaboard cities, of the establishment of telegraphic signal stations at outlying points off the coast, — at St. Johns and Sable Island, to watch the movement of areas of high barometer, upon which that of the succeeding 'low' so largely depends; and at Bermuda, Nassau, and various points in the West Indies and Windward Islands, that we may be forewarned of the approach and progress of the terrific hurricanes which, summer after summer, bring devastation and destruction along our Gulf and Atlantic coasts." Discussions like the present will contribute largely to arousing and keeping alive an interest in these researches, the practical and scientific value of which cannot be overestimated.

BOOK-REVIEWS.

Allen and Greenough's Latin Grammar. Revised by J. B. GREENOUGH and G. L. KITTREDGE. Boston, Ginn & Co. 12^o. \$1.35.

ADVANTAGE has been taken of the opportunity offered by the necessary recasting of the plates of this book to have such improvements made in it as the advance of grammatical knowledge and the experience of the schoolroom have shown to be advisable. The revisers have simplified the statement of principles, so far as a preservation of strict correctness would admit, but without any approach to a mechanical method of treating the science of language. Many explanations and suggestions, in text and footnotes, have been added to those given in previous editions, for the benefit of teachers and advanced scholars.

In the revision of this work, the needs of the classroom have evidently been kept constantly in view, resulting in great accuracy, combined with clearness and simplicity of statement. Although the matter of the book has been simplified, the size of the book has been increased, for simplification sometimes necessitates expansion. Many things taken for granted or merely suggested in the old edition have been expressly stated in this revision. Much new matter will be found, marking, in many particulars, a substantial advance. Thus, the chapter on word-formation has been entirely rewritten, many new points being presented; the treatment of the temporal particles has been recast; the section on reflexive pronouns has been rewritten; and the chapter on words consists in great part of new matter.

Some other subjects, in the treatment of which the new edition will be found more satisfactory than the old, and to which the especial attention of both student and teacher may be called, are included in that part of the book between Sections 248 and 332. There is also much new philological matter, which is nearly all printed in small-type notes, being intended more for the advanced student than the beginner.

Very numerous cross-references have been furnished in this edition, by means of which the ramifications of a construction,

etc., can readily be traced. In the same way references have been inserted in the grammatical analyses at the head of each chapter.

Typographically the present edition is a great improvement on the old. The pages are much more open and pleasing to the eye; section-headings have been used, and the paradigms have been printed in large full-faced type; important words in the examples are distinguished by the use of black type, and the size of the note type has been reduced, so that there is more difference to the eye than formerly between the text and the notes. The index of words and subjects is enlarged and revised, a separate index of verbs has been added, the glossary of terms has received additions, and the list of authors has been divided into periods. The list of important rules of syntax has been made more complete, and furnished with references to the body of the book, and in its present form will furnish pupils with a convenient and accurate summary. With a few exceptions at the beginning of the book, the section-numbers of the new edition correspond with those of the old, so that references to either are good for the other.

A Text-Book of General Astronomy. By CHARLES A. YOUNG. Boston and London, Ginn & Co. 8°. \$2.40.

THE present work is designed as a text-book of astronomy suited to the general course in our colleges and schools of science, and is meant to supply that amount of information upon the subject which may fairly be expected of every liberally educated person. Therefore it contains no proofs of astronomical theorems, except such deductions as can be explained by the use of elementary algebra, geometry, and trigonometry; its aim being to give a clear, accurate, and justly proportioned presentation of astronomical facts, principles, and methods in such a form that they can be easily apprehended by the average college student.

The author has fully accomplished his object, and his work is excellently adapted to the purposes of teacher and student, the matter being arranged systematically, and presented clearly. A great number of carefully selected illustrations enhance the value of the book and add to its clearness. After a brief introduction, in which the more important definitions are given, the author describes the principal astronomical instruments, the methods of observation, and the corrections of astronomical observations. After the discussion of a few problems of practical astronomy, such as determination of latitude and longitude, the dimensions and shape of the earth and the methods of its determination are described. After explaining the phenomena of the earth's orbital motion, the author proceeds to a description of the movements and physical character of the moon and sun. A special chapter is devoted to eclipses. It is only after the description of these movements that the author takes up the forces causing these motions. He discusses the law of gravitation and the important "Problem of Three Bodies," giving a very clear definition of perturbations. Then the planets are described. Before considering the fixed stars, comets and meteors, and the numerous unexplained phenomena and processes observed in these bodies, are treated in a comprehensive chapter. The book concludes with a discussion of the nebular hypothesis. This brief synopsis shows that the book is thoroughly methodical in its arrangement, and will therefore prove very useful for teachers and students.

The Australian Ballot System. By JOHN H. WIGMORE. Boston, Charles C. Soule. 8°. \$1.

THE object of this work is to describe the method of voting devised by Francis S. Dutton of South Australia, which seems likely to be adopted wherever representative institutions prevail. It has been practised in Australia for thirty years, and was adopted in England in 1872, and soon afterwards in Canada and Belgium. Last year it became the law in Massachusetts; and bills embodying its provisions have been introduced into the legislatures of New York and many other American States. Its essential characteristics are now pretty generally known. The names of all the candidates for a particular office are printed on the same slip of paper, and the voter marks a cross (x) against the name of the person he wishes to vote for. The ballots are printed at public expense, and distributed by public officers. The voter is required to mark his

ballot privately, so that absolute secrecy is secured. The object, and the effect wherever the system has been tried, is to put an end to bribery and intimidation. It being impossible to ascertain how a man votes, you cannot bribe or coerce him to vote as you wish. Mr. Wigmore here gives us a brief history of the system since its origination in Australia, with the arguments in its favor, and then presents in full the statute of Massachusetts, with the essential portions of the South Australian, the English, and several others. He gives also a specimen ballot according to the Massachusetts law, and also a full description, with illustrative cuts, of the mode of voting. Altogether his book contains the most complete and accurate account of the system we have anywhere met with, and may be cordially commended to all interested in political reform.

THE science of modern hypnotism is distinctly of French origin. The greatest of charlatans in this field, who disturbed the peace of so many credulous souls, won his fame and fortune in Paris; and it was in Paris that the successful steps were taken to atone for this injury by bringing these curious and startling phenomena into scientific repute. The movement, once started, grew rapidly, — indeed, with an almost morbid rapidity, — and within the last year or two the phenomena announced as demonstrated among the highly sensitive and very plentiful subjects of Paris seem marvellous, and threaten to overturn or vastly extend the tenets of science. Among much that is strange, much that is new, much that is false, and much that is true, it is difficult to know what to credit, and what to reject.

As has happened often before, the lookers-on are better judges than the players, and the Germans have assumed the attitude of critics. Not as liable as their enthusiastic neighbors to lose self-control in the whirl of interest, they have been calmly sifting the evidence, and assimilating the new to the old, rather than magnifying the novel into the mysterious. For this reason a review of recent German works upon hypnotism — of which those mentioned above form a typical selection, though only a selection in this rapidly increasing literature — may be of service in acquainting an American public with the true aspect of hypnotic research.

Dr. Hückel's pamphlet (1) is doubtless the most important on this list, and deals with the central point of discussion, — the issue between the school of Paris, headed by Charcot, and the school of Nancy, of which Dr. Bernheim may be declared the leader. The former hold that the hypnotic condition is induced by physical causes, such as passes, pressures, etc.; that there are three stages of hypnosis well differentiated, the passage from one to the other being accomplished by physical manipulations (closure or opening of the eyelids, pressure upon the vertex); that the phenomena assume their most typical form, and should be studied in hysterical patients; that the magnet has a distinct physical effect upon sensi-

tive subjects; that such also re-act to the physical effect of drugs when applied at a distance; and that even a certain degree of transfer of mental states is possible in a few subjects.¹ The school of Nancy recognize in all hypnotic states various forms of suggestibility: they regard the phenomena as purely psychical in origin; refuse to admit any supernatural powers or super-physical effects, such as those of the magnet; and explain all such points as due to more or less unconscious suggestion. Dr. Hückel proposes to show that the latter position is capable of accounting for all the observed facts, as well as the flaws in the conclusions and methods of the Paris experimenters. In the first place, all the effects claimed as of physical origin have been obtained by direct suggestion. This shows, at least, that the latter is as powerful an agent as the former. Moreover, the same manipulations have not produced the same results at Paris and elsewhere. Some comprehension by the subject of what is to result seems indispensable. But the important point remains of explaining the Paris results on the suggestion hypothesis. The keynote here is "unconscious suggestion" on the part of the operators, and shrewd anticipation on the part of the subjects. Take the alleged action of metals as an instance. In several cases gold alone brought about the desired effect. The most precious of the metals is, by a very natural analogy, regarded as the most efficacious, and this same preference will be quite general. How little specific influence the gold has, is shown by the fact that gold believed to be copper had no effect, while copper believed to be gold worked quite as well as the genuine metal.

When attention is directed to the patient's arm, it is not surprising that she should expect something to occur with the arm, and, if previously it has been rendered insensitive, it becomes so now. When attention is directed to the other arm, the phenomenon is "transferred." Another very vital influence is contagion. One subject sees the other, or hears of her actions, and exhibits the same results. An *esprit de corps* is thus formed, and this applies especially to the dozen subjects with whom Charcot has done almost all his work. It is almost impossible to realize how stringent the conditions must be to rule out unconscious suggestion. One's expression; tone of voice; manner; choice of words; evidence of interest, of surprise, of satisfaction, — any of these, entirely unconsciously given, may vitiate an entire experiment. A good case is that of a patient seated for three-quarters of an hour in close proximity to a magnet (unknown to herself) without exhibiting any signs of being affected by it, but re-acting promptly when informed of its presence. This must suffice to indicate the line of criticism of this most valuable pamphlet. It gives a surprising glimpse into the subtleness of psychic impressions, and gives an importance to the term "suggestion" not previously realized. One may take as the motto of the Nancy school the saying that another writer prefixes to his work on hypnotism, — "Possunt quia posse videntur."

In a subject that is comparatively new and unusually open to misunderstanding, general expositions and addresses will naturally find a public. To this class belongs the pamphlet by Dr. Sallis (2), with a convenient scheme of classifying the phenomena as motor (those that affect the muscles, such as rigidity, paralyses, contractions, and the like), as sensory (affecting the senses, such as anesthesia, special and general, suggested blindness, deafness, etc.), and vegetative (affecting organs normally removed from voluntary control, such as the formation of scars and blisters by imaginary burns, the slowing of the heart-beat, the oozing of blood through the skin). In addition to this exposition, the legal and curative effects are well described, and the pamphlet adds another to the many convenient summaries already extant. The point of view is that of the Nancy school throughout.

The essay of Dr. Forel (3), the eminent alienist and naturalist, is more general than its title would suggest. In order to acquaint the legal profession with the aspects of hypnotism of especial import to them, a general exposition is necessary. This is lucidly sketched with many forcible distinctions. Dr. Forel is a staunch adherent of the Nancy school, having derived his experience from Dr. Bernheim himself. He insists upon the close relation between hypnotic and mere normal states. When we ordinarily go to sleep,

we assume an accustomed attitude, in an accustomed place: all this is auto-suggestion. We suggest sleep to ourselves, and, unless distractions refuse to allow us the necessary concentration of mind, we follow the suggestion. Education, too, is largely a matter of suggestion skillfully applied. The educator's tact is the impressiveness of his suggestions. Some persons more readily subject themselves to the direction of others; they are the weak of will, that follow: while others seem Napoleon-like, born to command; their very manner enforces obedience.

The dangers of suggested crime in hypnotic conditions are just so much greater as the suggestions are more readily carried out. This is a serious problem, with which the law courts will soon be found to busy themselves. Especially in post-hypnotic suggestions, when the patient fully believes himself acting from his own motives, and sternly denies any possibility of suggestion, is the danger difficult to meet. The condition seems to demonstrate the truth of Spinoza's dictum, that the illusion of free will is merely the ignorance of the motives of our actions. Dr. Forel partly removes the danger by suggesting that none other but himself can hypnotize the subject; but even this is not a full guaranty. The topic is not yet in a satisfactory condition.

The pamphlet by Dr. Kraft-Ebbing (4) illustrates another mode of studying hypnotism: it is by a close observation of the phenomena in a single case. The patient has a remarkable history of hysteria, and has led an adventurous and irregular life. The right side of her body is insensitive, and she readily falls into the hypnotic condition by suggestion, or even of her own accord. Her control over involuntary functions is especially remarkable. If a characteristic shape, such as a letter of the alphabet, a pair of scissors, a glass cylinder, be held against the skin with the suggestion that it is red-hot, a burn and scar are formed in the shape of the object applied. The healing of this scar can be decidedly hastened by suggestion, and it can even be made to transfer itself to the symmetrically situated spot on the other side of her person. This is, of course, an extreme case. She responds to the action of a magnet (by violent contractions); but as this power is shared by any object in contact with a magnet, and only when the magnet is in the hands of Dr. Kraft-Ebbing, suggestion (perhaps by temperature changes) is the obvious explanation. The action of drugs at a distance failed entirely in her case. She easily accepts fantastic negative hallucinations, — such as that only the head and arms of a spectator are visible, the appearance causing great consternation, — as well as foreign personalities, changing her attitude and even her handwriting to suit the suggested character. Her time-estimates are strikingly exact. She will sleep an exact number of hours suggested, and so on. In brief, we have here a morbidly sensitive subject, and a typical case of the kind of hypnosis liable to accompany pronounced hysterical epilepsy.

The special study of the therapeutic aspects of hypnotism by the Freiherr von Schrenck-Notzing (5) gives one an admirable idea of the extensive activity in these studies. It is mainly devoted to a *résumé* of recent contributions. France and Germany are naturally most extensively noticed; but Belgium, Holland, Austria, Italy, Spain, England and America, Greece, Hungary, Poland, Russia, Norway, Sweden, Denmark, Switzerland, are all represented. There is a special review of hypnotism in France, and one in Spain, and a hospital for the cure of disease by hypnotism has been opened at Amsterdam. Much space is devoted to statistics of cures by hypnotism, the large percentage of successful treatments leaving little doubt of its therapeutic value. Its influence is most marked upon nervous diseases, though by no means restricted to such. The author is careful to caution against a too free use of hypnotism, and insists upon its restriction to professional specialists.

The part that the travelling mesmerist plays in the progress of hypnotism is altogether a dangerous one, and such public exhibitions have been prohibited in the chief countries of Europe. One point in their favor, however, is that they have so often served to arouse interest in the phenomena, and thus promote their scientific consideration. Dr. Hering's lecture (6) is a case in point. Its object is simply to satisfy local curiosity in the matter, — a laudable object, but very imperfectly carried out. His facts lack order, and the uncertain is jumbled together with the well-ascertained: — No

¹ These last three points would not be indorsed by all the adherents of the Paris school.

particular point of view is represented, the whole treatment being rather amateurish.

Very different in character is the address of Professor Miescher (7). After a clear history of hypnotism, showing its analogies with previous psychic doctrines, and with especial consideration of the work of Dr. Braid and Dr. Liebault, the author describes the chief well-established phenomena from the standpoint of the Nancy school. To this he adds a consideration of the will in hypnotized subjects. We have a state of automatism, in which every impulse must realize itself, but it is an automatism varying in degrees. Not all self-control is lost, any more than in sleep; the loss, too, is quite similar to what occurs in normal conditions. None the less it illustrates how closely a practical freedom of the will is connected with physical conditions, and how readily a state of irresponsibility may be induced.

The anonymous philologist introduced by Dr. Sallis (8) treats a question upon which the French have written much. They have advocated the introduction of hypnotism into the schoolroom to cure wayward children of bad habits. Laziness, pilfering, physical weaknesses, moral foibles, — all have yielded to this all-powerful agent; and an hypnotic moralization seems to be regarded as the automatic educator of the future. It is against this growing opinion that the author writes. He points out the obvious dangers of such a process, hints at cases in which children have learned to hypnotize one another, and urges that its use should be confined to distinctly abnormal children, requiring an abnormal treatment. Education has developed more natural methods of curing such defects, and so peculiar a cure as hypnotism should not be allowed to usurp their place.

As a final illustration of the ramifications of hypnotism, the last pamphlet on our list (9) will do service. The church enters the arena of hypnotism. A passing analogy between the trance states found among hypnotics and the religious ecstasies of saints is sufficient to arouse in Domprediger Steigenberger a fear lest the accredited church miracles will lose their hold upon the people. He thereupon denounces hypnotism as the work of demons, and proceeds to show how different is the basis of the miracles, and ends by claiming, that, inasmuch as hypnotism is avowedly incapable of explaining *all* the wonders of history, it is idle to consider it at all. With such different methods of reasoning, a sympathy between church and science in this topic could hardly be expected; but the shape this mutual misunderstanding takes is interesting.

From this review, however cursory, it is easy to gather some notion of the vastness of the researches still to be elaborated in this field, of the many-sided interests the problems present, and no less of the complicated pitfalls that beset their solution on all sides. Moreover, it may not be too hazardous to claim that one of the great controversies of hypnotism is about settled, — the issue between the Paris and the Nancy schools, the balance of evidence and opinion being decidedly in favor of the "suggestionists."

The English Restoration and Louis XIV. By OSMUND AIRY. (Epochs of Modern History.) New York, Longmans, Green, & Co. 16°.

THIS work labors under a disadvantage, in that its subject is not really an epoch. In English history, indeed, the age of Charles II. may be considered an epoch, though not a very important one; but in the general history of Europe it was rather the close of one epoch and the beginning of another. The earlier chapters of Mr. Airy's book deal with the wars of the Fronde in France, which resulted in the definite establishment of absolutism; while the rest of the work treats of the early years of Louis' reign, but breaks-off in the midst of his career. The author, however, has perhaps done as well as could be expected with such a theme, and he shows a clear grasp both of English and of European politics in the period of which he treats. The principal fault of the work is one common to most short histories, — an excessive amount of detail. This is specially conspicuous in the treatment of military affairs and court intrigues, the details of which are of little interest to the reader, though it must be admitted that court intrigues were more important in those days than they are now. Mr. Airy's style is good, and his judgment of men and events marked by good sense and impartiality. His chapters on the Fronde show how different that

movement was from the English revolution; and how inferior in interest; while, on the other hand, he does not fail to point out the ecclesiastical bitterness of the English Parliament after the restoration of the monarchy. In the general politics of Europe the chief interest centres, of course, in the ambitious schemes of Louis XIV., — in his contest with Spain and the Dutch Republic, on the one hand; and his intrigues with the king of England, on the other. The breaking-off of the narrative, however, in the flush of Louis' career, makes it impossible to give a complete picture; and the reader will have to turn to other volumes of the series for the conclusion of the story.

Master Virgil. By J. S. TUNISON. Cincinnati, Robert Clarke & Co. 8°. \$2.

IT is well known that during the middle ages a number of legends connected themselves with the name of Vergil. As a companion of the Devil, as a magician, and as a learned and competent physician, Vergil was presented at various times and by various writers. These legends and their history are curious in themselves, and interesting as indices of certain obscure phases of mediæval thought. Mr. Tunison has, at great labor, collected a vast amount of information on this subject, and now presents it in these interesting essays. The book is too learned to be popular, but it will have a cordial reception from men of letters.

AMONG THE PUBLISHERS.

THE February number (No. 40) of the Riverside Literature Series (published monthly at 15 cents a number by Houghton, Mifflin, & Co., Boston) contains "Tales of the White Hills" and "Sketches by Nathaniel Hawthorne." The "Tales of the White Hills" are "The Great Stone Face," a story about the Profile or Old Man of the Mountain, which is one of the most powerful and famous imaginative writings in all literature; "The Great Caruncle," founded on a wild and beautiful Indian tradition about the existence of a wonderful gem called by that name; and "The Ambitious Guest," an imaginative story of the memorable mountain-slide in Crawford Notch in 1826, which destroyed the whole Willey family, but left intact their house, from which they had fled in fright. The sketches comprise, "Sketches from Memory," "My Visit to Niagara," "Old Ticonderoga," and "The Sister Years."

— D. Lothrop Company will publish shortly, in their Story of the States Series, "The Story of Vermont," which will be of interest, as there has been no history of the Green Mountain State published for forty years. John L. Heaton, the author, is a well-known Brooklyn newspaper man, and is one of the many editors born and brought up in Vermont.

— Thomas Whittaker announces that the next volume in the Camelot Series will be "Essays of William Hazlitt;" in the Canterbury Poets, "Poems of Dora Greenwell;" and in the Great Writers, "Life of Schiller."

— William R. Jenkins has just published "A Chinese and English Phrase-Book for the Chinese to learn English," which is perhaps the first book with Chinese characters published in America. Its compilers are Dr. T. L. Stedman and K. P. Lee; and, while it is unpretentious in its character, it is excellently adapted to furnish Chinamen with a large vocabulary of colloquial phrases. The first edition of five hundred copies, though only just published, has been taken up so quickly that a second edition is already in the press.

— Alphonse Picard, of 82 Rue Bonaparte; Paris, is publishing an important historical work that will be of value to collectors of Americana. It is entitled "Histoire de la participation de la France à l'établissement des Etats-Unis de l'Amérique." The author is Henri Doniol, directeur of l'Imprimerie Nationale. Three volumes are now ready, covering the years 1775-79. These explain the efforts of the ministers of Louis XVI. to influence Spain to enter into the alliance against England, which went into effect after the first victories by the Americans over the English, — an alliance which later indirectly was the cause of the famous League of Nantes. The book is published by the French Government in connection with the Universal Exhibition which is to take place in Paris next

summer. It is intended to make the book a specimen of the work of the National Printing-Office.

— "The Last Journal" of the late Lady Brassey will be published here at once by Longmans, Green, & Co. It contains an account of the trip of the "Sunbeam" to India, Borneo, and Australasia. The publishers, at Lord Brassey's request, have sought to make this one of the most sumptuous volumes of late years. It is elaborately illustrated from drawings by Mr. R. T. Pritchett and from photographs. The woodcuts have been done by the best English engravers; and variety and novelty have been gained by the insertion of some forty monotypes executed in lithography.

— Sir Charles Dilke has been travelling in India, and will present the results of his observations in the March and April numbers of the *Fortnightly Review*. The articles will be of a military character, dealing with the strategical defences of the empire. This review is now issued from New York by the Leonard Scott Publication Company.

— "The Harvard Index for 1888-89" (Vol. XV.) is now ready. This is a complete university directory of officers and students, with complete athletic, base-ball, foot-ball, and boating records, and lists of officers and members of the college societies, the class secretaries, the officers of the Harvard clubs, the holders of academic honors, etc., and is published by the Harvard Index Company, Cambridge, Mass.

— The *Edinburgh Review* for January contains an article on Krakatoa, in which the German and English reports on the great eruption are reviewed.

— We learn from the *Publishers' Weekly* that a meeting of the executive committee of the Jewish Publication Society of America was held on the 21st of January, in the vestry-room of the Temple Emanuel, Fifth Avenue and Forty-fourth Street, New York. The following members were present: the Rev. Drs. Gottheil and Kohut of New York; the Rev. Drs. Jastrow and Krauskopf of Philadelphia; Judge Rosendale of Albany; Jacob H. Schiff, Professor Henry M. Leipziger, Benjamin F. Peixotto, of New York; Professor Charles Gross, Harvard College; Professor Cyrus Adler of Baltimore; Myer Sulzberger, Morris Newburger, S. A. Stern, S. Friedman, Ephraim Lederer, and Miss Mary M. Cohen, of Philadelphia. President Newburger presided, and submitted a roll of nearly one thousand members already subscribed in the States of New York and Pennsylvania. Committees were appointed on membership in the principal cities of the Union. Popular works on Jewish history and literature will soon be published. Membership costs \$3 a year; patrons, \$20; life membership, \$100. Messrs. Schiff of New York, and Guggenheim of Philadelphia, contributed \$5,000 each toward a "Michael Heilprin" fund, the interest only to be used. This fund, started by Jacob H. Schiff, is to be augmented to \$50,000.

— Under the heading "Another Learned Shoemaker," the *Publishers' Weekly* tells of Mr. John Mackintosh, author of "The History of Civilization in Scotland," who will write the volume "Scotland" in the Story of the Nations Series, who is in many respects a remarkable man. He was sent to work on a farm in his native county of Banff at ten years of age, and was subsequently apprenticed to shoemaking, at which trade he worked in various parts of Scotland for fourteen years. In 1869 he opened a small stationary shop in Aberdeen, "and there, on the shop counter," he once wrote, "amid all the noise and bustle of a stirring thoroughfare, the three volumes of my history were written and the proof-sheets corrected and revised, all being done while customers were coming in and out and constantly interrupting me."

— Albert S. Gatschet has published the second volume of his valuable book, "A Migration Legend of the Creek Indians," the first volume of which appeared three years ago in Brinton's Library of Aboriginal American Literature. The present volume is a reprint from the "Transactions of the Academy of St. Louis." It contains the carefully revised text of the speech of Chekilih, chief of the upper and lower Creek, delivered in 1737 at Savannah, before Governor James Oglethorpe, in the presence of several other chiefs. This speech was originally written on buffalo-skin, and sent, together with an

English translation, to England, where it was deposited in the Georgia office at Westminster. All attempts to find the original or the translation have been in vain. Fortunately, however, a German translation of this valuable document is extant. It was made by P. G. F. Von Beck, the commissioner of the Salzburg protestants, who, after having been expelled from their home, had immigrated to America. It has been reprinted in the well-known work of Samuel Ursperger, "Ausführliche Nachricht von den Salzburgernt Emigranten, die sich in Amerika niedergelassen haben." Dr. D. G. Brinton translated this speech back into English, and this translation served for the reconstruction of the original speech. Judge G. W. Stidham of Eufaula, Indian Territory, a Hitchiti Indian, undertook this arduous task in both the Creek and Hitchiti dialects. These two translations are contained in the present volume. The texts are followed by a short commentary and a very full dictionary of both dialects. A sketch of the Creek grammar was published in the first volume of this work. While these two chapters make the work indispensable for the linguist, the student of folk-lore will be greatly interested in the discussion of the track of the Kashihta migration. The present volume is accompanied by two valuable ethnological maps showing the location of Indian tribes at the time of the discovery. The work may be obtained from the author, P.O. box 591, Washington, D.C.

— *Shakespeareana* will begin in an early number a teachers' supplement, designed as an exchange among teachers for suggestions, opinions, and experiences in imparting instruction in English literature by means of the works of Shakespeare as a text-book.

— The *Fortnightly Review* for February contains a paper by Mrs. Lynn Linton on "Characteristics of English Women." It is the first of a series which begins historically. Mrs. Linton's papers on "Women in Greece and Rome" were a marked feature of the *Fortnightly* last year.

— *Blackwood's Magazine* for February opens with an article, accompanied with two maps, on "Major Barttelot's Camp on the Aruvimi," which will be found of interest in connection with recent events in Africa. Other notable papers are a review of the life of Titus Oates and the famous "Popish plot," a sketch of Minacoy, a sympathetic notice of Laurence Oliphant by Mrs. Oliphant, and a remarkable story of the Vigilance Committee at San Francisco, entitled "A Philanthropist." Additional chapters of the new novel "Lady Baby" are given, and the miscellaneous articles are of more than usual interest.

— S. A. Moran, principal of the Stenographic Institute, University of Michigan, Ann Arbor, has in preparation a "Type-Writer Dictionary," the object of which is to show the proper spelling and division into syllables of the more commonly misspelled and misdivided words.

— The Moses King Corporation, Boston, has in active preparation "King's Handbook of the United States." It is to contain 520 pages of text, maps, and more than 1,200 small original illustrations. There will be 50 full-page maps, one of each State and Territory, and a double page of the United States, printed in three colors. This book attempts to answer clearly and fully the demands for a general description and a popular history of the United States. The text is being prepared by M. F. Sweetzer, the Boston *litterateur*, and author of many guide-books, etc.

— The "Teachers' Manuals Series," published by E. L. Kellogg & Co. of New York and Chicago, has three new numbers: No. 11, "Argument for Manual Training," by Dr. Nicholas Murray Butler; No. 12, "Temperament in Education," by Dr. Jerome Allen; and No. 13, "School Hygiene," by President G. G. Groff of Bucknell University, Lewisburg, Penn.

— The *School Journal* of New York is publishing a number of valuable monthly four-page supplements, by Hughes, Quick, Allen, Butler, Groff, etc.

— In *The Phrenological Journal and Science of Health* for February, three women are sketched, and portraits of them given: viz., Mary A. Ward, author of "Robert Elsmere;" Margaret Deland, author of "John Ward, Preacher;" and the almost as well known Henrietta H. Skelton, author, and prominent advocate of temper-

ance reform. An analysis of the octogenarians of Massachusetts, and a story of heredity, are full of hints.

— "Sleeplessness in Infancy" is the subject of an article by Dr. M. Allen Starr, professor at the College of Physicians and Surgeons, New York, in the February number of *Babyhood*. "The Causes of Common Colds," by Dr. William H. Flint; "A Mother's Frights," by Mrs. E. W. Babcock; and "A Reformed Primer," by Mr. Louis Heilprin, — are the other leading articles.

— Ticknor & Co.'s February books include a novel by the author of "The Story of Margaret Kent," "A Daughter of Eve;" "Safe Building," by Louis De Coppet Berg, Series I.; and in their paper series, "The Desmond Hundred" (No. 51), by Jane G. Austin (ready Feb. 2), and "A Woman of Honor" (No. 52), by H. C. Bunner (ready Feb. 16).

— *The Contemporary Review* for February (New York, Leonard Scott Publication Company) contains an article entitled "The Bismarck Dynasty," which is unsigned, but is attributed to Sir Morell Mackenzie, and is supposed to have been inspired by the Empress Frederick. It reviews many of the incidents preceding the death of the late emperor, as well as those that followed that event. It is not sparing in its criticism of the present emperor, and calls him an apt pupil of a cynical master, who found no difficulty, moral or sentimental, in treating his mother in a fashion after Count Herbert's own heart, and in treating the Prince of Wales with such discourtesy as to prevent any intercourse between them. The article goes freely into the Geffcken and Morrier affairs.

— The new and forthcoming books of D. Appleton & Co. include "Capital: A Critical Analysis of Capitalist Production," by Karl Marx, translated from the third German edition; "Nature and Man: Essays, Scientific and Philosophical," by the late William Benjamin Carpenter, with an introductory memoir by J. Estlin Carpenter, M.A., and a portrait; "The Florida of To-day: A Guide for Tourists and Settlers," by James Wood Davidson, with railway and county map printed in colors, and illustrations; "Appletons' Cyclopædia of American Biography," edited by James Grant Wilson and John Fiske, Volume VI. (completing the work); "Mental Evolution in Man: The Origin of Human Faculty," by George John Romanes; "The Folk-Lore of Plants," by T. F. Thielton Dyer; "A Dictionary of Terms in Art," fully illustrated; "The Development of the Intellect," Part II. of "The Mind of the Child," from the German of W. Freyer (International Education Series); and "Co-operative Building and Loan Associations," by Seymour Dexter.

— A recent number of the *Geographisches Jahrbuch* contains a list of the geographical chairs in the universities of different countries. Germany, as before, takes the lead with nineteen chairs. In Austria-Hungary there are fourteen. Denmark has an extraordinary professorship. In France there are nineteen professorships and lectureships connected with the various universities, besides seven lectureships in special institutions. Great Britain figures in the list with two chairs. In Italy there are thirteen professorships; in Holland, one; in Russia, three; and in Switzerland, two.

— The Brooklyn Ethical Association have begun the publication of a series of lectures on the subject of evolution, under the general title of "The Modern Science Essayist;" and the first number of the series, by Daniel Greenleaf Thompson, on "Herbert Spencer," has just been issued by The New Ideal Publishing Company of Boston. It is popular rather than scientific, the object of the lectures being to propagate the evolution doctrine among the masses. Mr. Thompson is evidently a thoroughgoing evolutionist, not only in biology and history, but also in ethics and religion, and he puts Mr. Spencer on the highest pinnacle of fame, declaring him to be "much greater than either" Plato or Aristotle, though he condescendingly admits that these men were "really worthy Greeks, who would be considered good philosophers, as philosophers go in our time." A part of this lecture, or essay, is occupied with biographical and personal anecdotes of Mr. Spencer, which every reader will find interesting; and the rest gives a brief summary of his leading doctrines, with special stress on their religious and ethical bearings. The second paper of the series will relate to Darwin, while the

succeeding ones will deal with various aspects of the evolution philosophy.

— Professor Nicholas Murray Butler has given to the public his "Argument for Manual Training," originally read before the American Institute of Instruction, and the pamphlet is published by E. L. Kellogg & Co. of New York. Professor Butler is an enthusiast on the subject of which he treats, and declares that "a movement at once so philosophic and so far-reaching as that in favor of manual training has not come into educational thought since Comenius burst the bonds of mediævalism two and a half centuries ago." He holds that under our present system of education there is no adequate training of the executive and constructive faculties, and that the defect can only be supplied by regular manual exercises in the common schools. His arguments in favor of the system are not specially new, but they are clearly and forcibly presented, and will be interesting to educators everywhere. An appendix to the pamphlet gives a brief summary of the course of manual training that has been followed for some time in the schools of Jamestown, N.Y., so that those not already familiar with the system can see what it is.

— Mrs. Oscar Wilde appears as a contributor to the *Woman's World* for March (Cassell & Company), as does the famous novelist "Ouida" and the equally famous author of "How to be Happy though Married."

— In *The Truth Seeker* of Feb. 16 will be published "The Limitations of Toleration," a discussion between Col. Robert G. Ingersoll, Hon. Frederick R. Coudert, and Gov. Stewart L. Woodford, before the Nineteenth Century Club of New York, stenographically reported for *The Truth Seeker* by I. N. Baker. The publication of this discussion has been delayed from various causes. F. R. Coudert is a Roman Catholic, and one of the best orators of New York. Gov. Stewart L. Woodford is a Protestant, and a splendid speaker. The discussion is the only oral public debate ever engaged in by Col. Ingersoll. He had the opening and the closing of the argument, and made two of his most forcible and eloquent speeches. President Palmer's introductions of the orators will also be given.

— The three methods employed for making window-glass will be described and pictured in *The Popular Science Monthly* for March by Professor C. Hanford Henderson of Philadelphia. Dr. Andrew D. White will conclude the subject of "Demoniacal Possession and Insanity," which forms one of his "New Chapters in the Warfare of Science," now publishing in that magazine. The forthcoming article will tell how the Roman Catholic, Lutheran, and Calvinistic clergy vied with each other, in exorcising and persecuting the unhappy victims of insanity, and how medical science slowly introduced more humane treatment, and finally drove back superstition from this part of the great battle-field. The relations of "Competition and the Trusts" will be discussed by Mr. George Iles, who first points out the great waste of effort and other losses, due to competition, and takes the ground that the trusts have, on the contrary, reduced the costs of business, and hence, if duly regulated, can serve the public better than competition. Many educators, who would be glad to use science in the training of young pupils if they knew just how to go about it, will be interested in the practical directions given in an article on "Natural Science in Elementary Schools," by J. M. Arms. Mr. Arms writes with a full appreciation of the true aims of science-teaching, and from an experience of ten years in the work.

— The *Nineteenth Century* for February (New York, Leonard Scott Publication Company) contains Professor Huxley's famous article on agnosticism. An interesting symposium is given on noticeable books, with contributions by Mr. Gladstone, Frederic Harrison, Rowland E. Prothero, W. S. Lilly, Augustine Birrell, Hamilton Aidé, the Rev. Dr. Jessopp, and Mr. Morley. Further comments are given on the relation of examination to education, by W. Baptiste Scoones, Hon. Auberon Herbert, Sir Frederick Pollock, Sir Joseph Fayer, Francis Galton, Dr. Priestley, and the Bishop of Carlisle. Among other contributions is one from his Majesty the King of Sweden and Norway.

LETTERS TO THE EDITOR.

Twenty copies of the number containing his communication will be furnished free to any correspondent on request.

The editor will be glad to publish any queries consonant with the character of the journal.

Tornadoes: Fact vs. Fiction.

THERE is no subject in meteorology of more absorbing interest than this. As our knowledge of the environment of tornadoes increases, there must necessarily be modifications in our views of their origin. One of the more recent and most significant of these changes has been the transference of the cool northerly wind, meeting the warm south wind, from the earth's surface to the upper regions, where it is said to overflow the lower current, and produce an unstable equilibrium in the atmosphere. It would seem as though no subject can demand, more strongly than this, a solid substratum of fact; and yet, strange to say, the theories and speculations about these terrible visitors have been far more extensive than the facts. This seems a favorable time to state a few of the more prominent facts and seeming fictions. The facts are these:—

1. It has been well said that the most important recent development has been the fact that tornadoes occur, not at the centre of a general storm, but about four hundred miles to the south-east. This fact was known fifteen years ago, but was first strongly emphasized in March, 1884.

2. All currents in this region, even up to a great height, are from the south before the tornado, as is well known from observations of the upper clouds.

3. The tornado invariably moves to the north-east; and if, as some believe, it takes its motion in the upper current, that must be from the south-west, and cannot be from the north even after the tornado.

4. The pressure rises in a tornado, as has been observed a few times in it, and it invariably rises at the centre of a thunder-storm, which frequently develops into a tornado.

5. That some other force than a violent gale blowing into a partial vacuum is concerned in the destruction, is well shown by the fact, that of two free barrels side by side, one of which was empty and the other full, the former was left undisturbed, while the other was completely obliterated. Fowls have been stripped of their feathers, and people deprived of their clothing, which could not be brought to pass by the most violent gale.

6. The tornado is extremely sudden, and, advancing without any warning, it interjects itself into a region of gentle southerly winds. After it has passed, the southerly wind almost at once again predominates. The whole appearance is as though a disturbance, largely having its own source of energy, had suddenly projected itself into a quiet air, and passed on without bringing about any but a momentary change.

7. Its velocity is nearly double that of the accompanying general storm.

8. Numerous thunder and hail storms are an invariable accompaniment.

A few fictions are the following:—

1. Professor Ferrel states on p. 327, "Recent Advances in Meteorology," that in the tornado there is an unstable equilibrium due to "the large vertical gradient of temperature decreasing with increase of altitude."

2. Mr. Finley, in *Science* of Feb. 1, thinks that this same condition must be found, not in the tornado, but in the region just around it.

3. This abnormal decrease of temperature is due to cold air overrunning warm. This is really an impossible condition, since the denser cool air must always under-run that which is lighter and warmer. That a most extraordinary decrease of temperature and most extreme unstable equilibrium, possibly five hundred times as great as can ever occur under natural conditions, does not produce a destructive whirl, advancing scores of miles from its origin, is well shown by the seas of fire extending many square miles in forest clearings. Here there is a temperature at least 1000° higher than that of the air two or three hundred feet above it. There are

occasional whirls set up over such a fire, but they are short-lived, and extend only to its edge.

4. There is a violent uprush of air at the tornado centre. As we have just seen, the tornado is not at the storm-centre, but four hundred miles to the south-east, where there is no rising tendency in the air.

5. There is a uniform flow of northerly upper currents over an extended region, and tornadoes are produced at spots one hundred miles apart by the breaking-through of the warm lower air.

6. The tornado, in its onward motion dipping here and there for one hundred miles and more, has its energy kept up by a continual upsetting of the equilibrium, conveniently occurring just in front of it exactly at the moment of its advance, and nowhere else. These latter certainly have no facts to sustain them, and must be regarded as impossible or highly visionary till observations in the cloud region give still further facts. Until these facts are had, it is unsafe to theorize.

H. A. HAZEN.

Washington, Feb. 4.

A Deadly Gas-Spring in the Yellowstone Park.

THE familiar fable of the upas-tree, living in a valley of death wherein all life was killed by its deadly exhalations and the ground was strewn with the bones of its victims, has been proven, like many a traveller's tale, to be a highly colored and exaggerated account of a natural phenomenon. The upas-tree is now well known to have poisonous sap, but not poisonous vapors. But the story survives in the accounts given of the Death Valley of Java, which it was long believed no traveller could cross, "wherein every living being which penetrated the valley falls down dead, and the soil is covered with the carcasses of tigers, deer, birds, and even the bones of men, all killed by the abundant exhalations of carbonic-acid gas, with which the bottom of the valley is filled." Such is the description given by Lyell¹ of this famous valley; while another locality is described as a place where "the sulphurous exhalations have killed tigers, birds, and innumerable insects, and the soft parts of these animals are perfectly preserved, while the bones are eroded and entirely destroyed. The researches of Junguhn² have shown that these accounts are much exaggerated, the "valley of death" being a funnel-shaped depression but one hundred feet in diameter, instead of a valley half a mile across. In the bottom of this depression there is a hole about fifteen feet in diameter, from which gaseous emanations are given out, which at times accumulate to a depth sufficient to envelop and suffocate animals on the bottom of the hollow. Repeated visits by Junguhn, extending over a period of twelve years, showed that the amount of gas varied greatly from time to time, but rarely ever rose over two feet and a half above the bottom. At the time of his earlier visit, he found the body of a Javanese native in the depression, but experienced no difficulty or oppression while there himself. This same body was still undecomposed, owing to the preservative effect of the layer of gas, when he repeated his visit eighteen months later. The only other remains seen during his subsequent visits were the carcasses of six swine which were decomposed and putrid. At this time the absence of the gas was shown by the presence of a crow feeding upon the dead bodies.

Though thus shorn of much of its former glory, this Pakaraman, or poison-hole, is the largest and most dangerous of the gas-springs or mofettes of Java, and indeed of the world, and really deserves the title of a natural death-trap. Though such emanations are common in all volcanic regions, this has been the only place known where the gases have accumulated, and caused the death of the larger animals.

In the Yellowstone National Park, now so well known as the wonderland of America, there is a place equalling this famous death valley, and where the gaseous exhalations have proved fatal to numerous bear, elk, and many smaller animals.

This place, to which the appropriate name of "Death Gulch" is given, was discovered by the writer during the past summer (1888), while making a geological examination of the region for Mr. Arnold Hague, the geologist in charge of the survey of the park. It is situated in the extreme north-eastern portion of this reservation, a

¹ Principles of Geology, 1878, i. p. 590.

² Java Seine Gestalt, etc., German translation by Hass Karl, ii. p. 202.

short distance south of the mail-route, which, leaving Lamar River, follows up Soda Butte Creek to the mining-camp of Cooke City. In this region the lavas which fill the ancient basin of the park rest upon the flanks of mountains formed of fragmentary volcanic ejecta, the tertiary andesitic breccias, which rest in turn upon nearly horizontal paleozoic strata; while the hydrothermal forces, which are represented by the geysers and hot springs of the central portion of the park, where the lava-sheet is thicker, show but feeble manifestations of their energy in the almost extinct hot-spring areas of Soda Butte, Lamar River, Cache Creek, and Miller Creek. Although hot water no longer flows from the vents of these areas, the deposits of travertine, sinter, and decomposed rock, attest the former presence of thermal springs. Gaseous emanations are now given off, however, in considerable volume, producing extensive alteration in the adjacent rocks, and giving rise to sulphurous deposits.

It is at one of these places that the fatal ravine is found. Situated on Cache Creek, but two miles above its confluence with Lamar River, it is easily reached by a horseback ride of some five miles from the mail station of Soda Butte. The region is, however, rarely visited; for hunting is forbidden in the park, while the place has not been known to present any attraction for the few visitors who pass near it on their way to the well-known Fossil Forests and the weird scenery of the Hoodoo basin.

An old elk-trail, which runs along the north bank of Cache Creek, affords easy travelling, and leads to a little opening in the pine-forest bordering on the stream. In the centre of the meadow is a shallow depression, once the bed of a hot-spring pool, now dry, and covered with an efflorescence of salt, making it attractive to the elk and other game of the region as a "lick." The banks of the creek opposite this meadow and below it are covered with the ancient hot-spring deposits, which are very dense and hard, and at the borders of the stream have been polished by the action of the water until the surface shines like glass. A hot-spring cone half washed away by the creek, and a mound of altered travertine on the opposite bank, show the character of the ancient hot-spring water, the rippled surface of the deposit being exactly like that of the beautiful terraces and slopes of the Mammoth Hot Springs. At present, however, the only thermal action is the emission of a little tepid sulphurous water at the edge of the stream. On the other hand, the gaseous emanations are very striking and abundant.

In the middle of the creek, which here forms a deep pool about thirty feet across, bordered by the polished calcite already mentioned, the water boils up furiously at several places. This water is, however, quite cold; and the "boiling" is caused by the very copious emission of gas, mainly, no doubt, carbonic acid, though containing some sulphuretted hydrogen, since its smell is quite noticeable, and the water is slightly turbid with particles of sulphur, which also coat the sides and bottom of the pool. Rising through the water of the creek, the great amount of gas given off at this place is easily appreciated, but equally copious emanations may occur from the deposits and old vents near by, which, being invisible, remain unnoticed.

Above these deposits of altered and crystalline travertine, the creek cuts into a bank of sulphur and gravel cemented by this material, and a few yards beyond is the debouchure of a small lateral gully coming down from the mountain-side. In its bottom is a small stream of clear and cold water, sour with sulphuric acid, and flowing down a narrow and steep channel cut in beds of dark gray volcanic tuff. Ascending this gulch, the sides, closing together, become very steep slopes of white decomposed rock, the silicious residue formed by the decomposition of the rocks by acid vapors or waters. The only springs now flowing are small oozes of water issuing from the base of these slopes, or from the channel-bed, and forming a thick, creamy, white deposit about the vents, and covering the stream-bed. This deposit consists largely of sulphate of alumina. The slopes show lowland areas where sulphur has been deposited by the oxidation of sulphurous vapors, but no extinct hot-spring vents were found. About one hundred and fifty feet above the main stream, these oozing springs of acid water cease; but the character of the gulch remains the same. The odor of sulphur now becomes stronger, though producing no other effect than a

slight irritation of the lungs. The gulch ends, or rather begins, in a "scoop" or basin about two hundred and fifty feet above Cache Creek; and just below this we found the fresh body of a large bear, a silver-tip grisly, with the remains of a companion in an advanced state of decomposition above him. Near by were the skeletons of four more bears, with the bones of an elk a yard or two above; while in the bottom of the pocket were the fresh remains of several squirrels, rock-hares, and other small animals, besides numerous dead butterflies and insects. The body of the grisly was carefully examined for bullet-holes or other marks of injury, but showed no traces of violence, the only indication being a few drops of blood under the nose. It was evident that he had met his death but a short time before, as the carcass was still perfectly fresh, though offensive enough at the time of a later visit. The remains of a cinnamon bear just above and alongside of this were in an advanced state of decomposition, while the other skeletons were almost denuded of flesh, though the claws and much of the hair remained. It was apparent that these animals, as well as the squirrels and insects, had not met their death by violence, but had been asphyxiated by the irrespirable gas given off in the gulch. The hollows were tested for carbonic-acid gas with lighted tapers without proving its presence; but the strong smell of sulphur, and a choking sensation of the lungs, indicated the presence of noxious gases, while the strong wind prevailing at the time, together with the open nature of the ravine, must have caused a rapid diffusion of the vapors.

This place differs, therefore, very materially from the famous Death Valley of Java and similar places in being simply a V-shaped trench, not over seventy-five feet deep, cut in the mountain-slope, and not a hollow or cave. That the gas at times accumulates in the pocket at the head of the gulch, is, however, proven by the dead squirrels, etc., found on its bottom. It is not probable, however, that the gas ever accumulates here to a considerable depth, owing to the open nature of the place and the fact that the gulch draining it would carry off the gas, which would, from its density, tend to flow down the ravine. This offers an explanation of the death of the bears whose remains occur, not in this basin, but where it narrows to form the ravine; for it is here that the layer of gas would be deepest, and has proven sufficient to suffocate the first bear, who was probably attracted by the remains of the elk, or perhaps of the smaller victims of the invisible gas; and he, in turn, has doubtless served as bait for others who have in turn succumbed. Though the gulch has doubtless served as a death-trap for a very long period of time, these skeletons and bodies must be the remains of only the most recent victims; for the ravine is so narrow and the fall so great, that the channel must be cleared out every few years, if not annually. The change wrought by the water during a single rain-storm, which occurred in the interval between my first and second visits, was so considerable that it seems probable that the floods of early spring, when the snows are melting under the hot sun of this region, must be powerful enough to wash every thing down to the cone of *débris* at the mouth of the gulch.

Gaseous emanations are very frequent in volcanic countries, and may be either temporary or permanent. The former are, as is well known, particularly abundant after volcanic eruptions. The gases emitted from fissures in the flanks of Vesuvius are said to have killed thousands of hares and pheasants, and whole herds of cattle have been suffocated by volcanic gas given off near Quito. The permanent emissions of gas, such as the mofettes of Italy, the Laacher See, and the Auvergne, remain unchanged, however, for centuries. Where carbonic-acid gas is evolved from a fairly uniform surface, it is quickly diffused into the atmosphere upon the slightest movement of the air; but the case is quite different when the gas is emitted in caves or hollows in the ground. In such places it accumulates, because of its density and slow diffusion, until the hollows are filled to the brim, any excess being quickly diffused as from a level surface. Small hollows of this kind occur in the travertine deposits of the Mammoth Hot Springs of the park, and near the Hot Lakes of the Lower Geyser basin. In these places, small birds, mice, etc., attracted by the warmth of the vapors, or the dead insects, are often suffocated by the gases. Such hollows resemble the mofettes of the Laacher See in Germany, where

dead mice and birds are always found, and are common in other regions as well. The well-known Grotto del Cano, near Naples, is the most familiar example of such accumulations of carbonic-acid gas; and visitors are frequently entertained by the asphyxiation of a poor dog, while the guide, whose head rises above the gas, is not affected by it. Death Gulch is, however, without a peer as a natural bear-trap, and may well be added to the list of the wonders of the Yellowstone Park.

WALTER H. WEED.

U. S. Geol. Surv., Washington, Jan. 30.

A New Method for the Microscopical Examination of Water.

In making microscopical¹ examinations of potable waters, it is entirely impracticable, on account of their relative purity, to proceed directly. Repeated examinations of random samples might yield absolutely nothing, although filtration of a few cubic centimetres through a fine cloth might show that in the same water there were abundant microscopic forms.

The importance of being able to ascertain the presence of these microscopic organisms, and to determine their number and species in any given sample of water, is self-evident. It is important, not only from a purely scientific, but also from a sanitary, point of view, to know precisely what is contained in drinking-water. Again: large manufacturing interests are dependent upon the purity of the water supplied to them through filters or otherwise, while many large towns depend upon the efficiency of filters for the purity of their water-supply. A microscopical examination of the water before and after filtration shows very clearly the actual work which the filter accomplishes, in a way that it is impossible for chemical analyses to do. From a scientific and sanitary point of view, microscopical examinations are accordingly of great value both as a means for the study of the organisms themselves, and of the influences of changes in the water upon their growth, life, and death, as well as the counter effects produced upon the water by them. For making such examinations there have been hitherto, so far as I know, but two methods employed. One of these is that proposed by Dr. J. D. McDonald in his "Guide to Microscopical Examination of Water" (J. & A. Churchill, London, 1883). In this method the sample to be examined is put into a tall glass cylinder, at the bottom of which is a watch-glass suspended by a platinum wire. This is allowed to stand for forty-eight hours, in order that the matters held in suspension may settle into the watch-glass at the bottom. The upper water is then siphoned off, and the contents of the watch-glass examined under the microscope.

The other method, the origin of which I do not know, is used at present by the Massachusetts State Board of Health. In this method a given quantity of water is passed through a fine linen or cotton cloth tied to the lower end of a funnel. After the water has passed through it, the cloth is removed, and cautiously reversed over the end of a glass tube, the numerous objects which have been caught upon the cloth being now upon the outside. A slide is then placed under the cloth, and a puff of air blown through the tube. The moisture contained in the cloth collects in a drop, which falls upon the slide, carrying with it theoretically the materials filtered out of the water. The slide is then examined under the microscope, and the organisms obtained counted. Both these methods are open to very serious objections, and are so crude that no fair estimates of the number of organisms contained in a given sample of water can be formed. In the case of the first method, I have found that by no means all of the microscopic organisms settle to the bottom, even when the water is left standing a much longer time than forty-eight hours, as there are many which have about the same specific gravity as water, and consequently do not settle. This source of error becomes greater in proportion as the water to be examined becomes purer. In the case of ordinary drinking-water, the sediment is very inconsiderable, although there are large numbers of organisms held in suspension. Under ordinary circumstances, water left standing in this way gives an excellent opportunity for the organisms present to increase. Especially is this the case with filtered water, where the increase is surprisingly rapid. From this it is plain that the sediment in the watch-glass does not represent what was originally in the water, but only

a small part of that amount plus a part of the increase which has since taken place. In the second method, if the cloth be examined microscopically after presumably all the microscopic organisms have been removed, it will often be found that a very large number are stuck in the meshes of the cloth.

For these two methods I have substituted one which, although far from perfect, gives much better results. I have now been using it for four months in making microscopical examinations of water for the city of Boston.

The new method is as follows. A known quantity of water (I have found 100 cubic centimetres a convenient unit) is put into a funnel in the tube of which is half an inch in depth of sand (24 to 30 grains to the inch). The sand is held in place by a stop made of a roll of brass wire gauze, which gives free passage to the water, while it holds the sand in place. Through this the water is filtered, the sand holding back the microscopic forms. The experiments which I have tried, to test whether all the organisms are removed or not, have proven conclusively the efficiency of the sand in holding back all the microscopic organisms in the water. After all the water has passed through, the stop is removed, and one cubic centimetre of distilled water (the water which has just been filtered will answer as well) is thrown into the funnel by means of a pipette. This washes the sides of the funnel, and carries the sand with it down into a watch-glass which is held underneath to receive it. On falling into the watch-glass, the grains of sand separate and sink to the bottom, leaving the lighter organisms which have been caught between them mostly suspended in the water. By stirring this wash-water a more even distribution of the organisms is obtained, and, if any have been carried to the bottom by the falling sand, they are liberated; so that if the wash-water be poured off, and the sand examined under the microscope, it will be found that there are no more organisms among it than might be expected. Some of the water standing above the sand is immediately transferred to a slide, containing a chamber the capacity of which is one cubic millimetre. All the microscopic organisms contained in this chamber are then counted under the microscope, and from the result the total number of organisms in the original sample is computed. I have found this cubic millimetre surprisingly representative of the whole mass of the wash-water, as far as the numbers go, although, as would naturally be expected, the species vary largely in different samples.

This method, as the first which can fairly be called quantitative, opens up a new field, having wide and practical applications. It is to be hoped that microscopical examinations may hereafter take their proper place alongside of bacteriological and chemical analyses, to which they must form important adjuncts.

Insurance.

DELAY IS DANGEROUS.

We call attention to the new form of Accident (indemnity) Insurance policies, which are written by the Merchant's Casualty Insurance Association, 27 Park Row, New York City, John S. Purdy, Secretary. These policies cover weekly allowances of from \$10 to \$25, according to occupation, at a cost of only \$6 a year exclusive of the cost to join, which is \$5 payable once only. The public, as a rule, carry life insurance, and the ordinary accident policies issued by companies, paying a sum in case of death, is not so desirable as one of these indemnity policies in case of accidents, which are so plentiful in this fast age with its railroad horrors, fast driving, electric wires and other countless forms of danger to which the public is constantly exposed. The fact of the Association having no unpaid claims, and its having just passed an examination by the Insurance Department of New York State, shows that the management is liberal with its policy-holders and conservative in its action. The Association also desires to secure energetic Agents in every village and town, to whom territory and favorable terms will be given.

WHY YOU SHOULD USE

Scott's Emulsion

of **Cod Liver Oil** WITH
HYPOPHOSPHITES.

It is used and endorsed by Physicians because it is the best.

It is Palatable as Milk.

It is three times as efficacious as plain Cod Liver Oil.

It is far superior to all other so-called Emulsions.

It is a perfect Emulsion, does not separate or change.

It is wonderful as a flesh producer.

It is the best remedy for Consumption, Scrofula, Bronchitis, Wasting Diseases, Chronic Coughs and Colds.

Sold by all Druggists.

SCOTT & BOWNE, Chemists, N. Y.

SCIENCE

FRIDAY, FEBRUARY 22, 1889.

PRACTICAL ELECTRIC-RAILWAY PROPULSION.

It is a striking indication of the overcrowded surcharged state of modern life that events of extreme significance and momentous importance take place without exciting more than a ripple on the surface of its current, so rapid, deep, and vast it is.

Such an instance is depicted in the accompanying illustration, which is of the electric locomotor "Benjamin Franklin," with its eight-car train, now running upon the Ninth Avenue Elevated Railway in New York City.

With these perfectly intelligible and merely fortuitous differences, the service of the steam and electric train is identical.

What the "Franklin" has achieved in its experimental work may be briefly stated as follows: It has drawn eight empty cars—making, with the locomotor, 122 tons in train—up a gradient of nearly two per cent at 7½ miles per hour, developing, in so doing, over 120 horse-power; it has taken four cars up the same gradient, with the average load of passengers, or 70 tons in train, at 15½ miles per hour, more than two miles faster than the schedule speed of the steam-locomotives; it has maintained speed of 30 and 25 miles per hour with trains of two and three unloaded cars.

All this has been done without the slightest accident or delay of

DAFT ELECTRIC MOTOR AND TRAIN OF EIGHT CARS ON THE NEW YORK ELEVATED RAILWAY.

To be literally accurate, it should be said that the service is confined to certain hours of the day, that only three or four cars are used in it, and that passengers are only taken on at the termini; viz., Fourteenth and Fiftieth Street stations.

The reasons for these limitations are as follows: Since the locomotor has to be switched from one end of the train to the other at each terminus, only that portion of the day is available in which the headway of the steam-trains, among which it runs, affords sufficient time for the operation. In the many hundred miles that the "Franklin" has made, it has never delayed a steam-train or deranged their succession. The cause of not stopping at intermediate stations is, that, as the locomotor has at present no means of utilizing the air-brakes,—though this lack is being provided for,—the necessary reduction of speed near every station, to permit of the trains being brought to rest by hand-brakes, would so trench upon the time needed for switching, at each terminus, as to endanger delaying steam-trains, or sacrificing trips to avoid so doing.

any kind, and with every indication of the locomotor still being well within its ultimate capacity. For facility, certainty, and promptness of manipulation, nothing more could be asked for.

Such a chapter of success as this, quite apart from its technical and commercial significance, ought surely to have been fittingly recognized. The first grand scale electric locomotor in the world's history, and the first ever brought into direct competition with steam-locomotives, after doing all that they do, and triumphantly complying with every imposed condition, elicits little more from the technical press than a few perfunctory allusions alike distinguished for incompleteness and inaccuracy.

The gist of one notice was dissatisfaction that the "Franklin," in spite of its complete success, was not something else than what it is, and an inane caution, that, notwithstanding its ready disposal of every suggested test, and easy rivalling of the steam-locomotives in all respects, it would be advisable to lay this practical, actual entity on the shelf, and wait for the possibility of something better turning

up, in shape of the inchoate *eidolon-fori* of some nameless dreamy inventor.

Technical journalism, in the field of electrical power at least, would seem to be at a low ebb in New York.

As for the current-generating plant and conductive system, they, as well as the "Franklin," are entirely of the Daft design. The former is on Fifteenth Street, about midway between Sixth and Seventh Avenues, and wires of suitable size convey the current to and fro between the stationary plant and the track-conductors. A steam-engine of 250 horse-power drives four dynamo-generators of 50 horse-power each.

The conductor is a copper rod, five-eighths of an inch in diameter, sustained by insulators attached to the guard-timbers alongside the track. Elastic copper "brushes" pressing against and sliding along this rod convey the current to the electro-motive mechanism, which it traverses, causing revolution by its passage, and completes its circuit through the wheels and track-rails.

Time and space will not admit of an analysis of the inherent and incidental economy of electric propulsion; but "he who runs may read," whether or no the preference lies with the light, comparatively noiseless, cleanly electro-locomotor, devoid of steam, smoke, cinder, and hot *jets d'eau*, or the ponderous, clamorous, steam-locomotive, wasteful of fuel, destructive of road-bed, and inherently hampered by nuisances from which its electric rival is absolutely free.

X.

THE WORTHINGTON INDEPENDENT CONDENSER.

THAT the practical results attained by condensing-engines should approximate to those that theory indicates, it is important that the condensing-apparatus employed should be the most efficient possible; that it should maintain the highest vacuum, with the least cost of production; that it should be regular and reliable in action, and simple in construction; and that its application to the engine should be unaccompanied by any risk of accident. These exacting requirements, it is claimed, are fully met by the condenser shown in the accompanying illustrations.

Exhaust-steam from an engine enters a vacuum with a velocity of about 1,900 feet per second; and water, under atmospheric pressure, with a velocity of 47 feet a second. Excepting the machine herein described, it may be said that in all forms of jet-condensers operated by air-pumps, the injection-water and the water from the steam fall to the bottom of the condensing-chamber, come to a standstill before entering the pump, and consequently lose the valuable momentum acquired when entering the vacuum space. In this condenser, however, the construction and arrangement are such that the momentum of the steam and water is conserved, and this force is utilized to assist the pump in its work.

By a careful adaptation of the injector principle, it is possible, in an experimental way, to produce a vacuum, of low degree however, without the use of a pump at all,—simply by the momentum given to a flow of water by the impact of the exhaust-steam at the point of condensation. A condenser dependent upon this alone is not practical, because of its small range of action, the inferior vacuum it obtains, and the low temperature of the discharge-water. A change of the amount of steam to be condensed disturbs the theoretical conditions, and renders this kind of apparatus too unreliable in practice. It is plain that the addition of a duplex pump to the discharge of such an ejector condenser perfects and governs its action. As the momentum of the water is not impaired, the highest economy of operation is reached.

In this condenser, the air set free by the condensation of the steam is intermingled with the water. The pump has the same regularity of motion that is characteristic of Worthington pumping machinery; in fact, it acts as a water-pump, although the water is aerated. There is here a great distinction between this condenser pumping aerated water, and an air-pump pumping air and water unmingled. In the latter case, the air-pump has a varying and irregular duty to perform, and the inevitable result is an irregular and slamming movement.

The lower of the accompanying illustrations is a longitudinal section of one side of the condenser-pump, and also a section of the condenser-cone, spray-pipe, exhaust-elbow, and injection-elbow,

A is the vapor-opening, to which is connected the pipe that conducts to the apparatus the steam or vapor that is to be condensed, and in which a vacuum is to be made and maintained. The injection-water used to produce the condensation of the steam or vapor is conveyed by a proper pipe attached to the injection-opening at *B*. *C* is the spray-pipe, and has at its lower extremity a number of vertical slits, through which the water of injection passes, and becomes spread out into thin sheets. The spray-cone *D*, by means of its serrated surface, breaks the water passing over it into fine spray, and thus insures a rapid and thorough intermixture with the steam. This spray-cone is adjustable by means of the handle *E*. The piston-pump *G* is of the well-known Worthington type; built, however, with especial attention to the requirements of the service which is now being considered. *HH* shows the position of the induction, and *II* of the education valves. *J* is the discharge-opening. At *K* may be seen the steam or engine end of the machine, the standard form used on all Worthington steam-pumps. The steam-valve is an ordinary slide-valve, working upon a flat surface over ports or openings. The motion of this valve is produced by a vibrating arm, *L*, which swings through the whole length of the stroke with long and easy leverage.

This valve motion is a prominent feature of the Worthington independent condenser. To it is due the complete exemption from noise or concussive action. The two pumps are placed side by side, and so combined as to act reciprocally upon the steam-valves of each other. One piston acts to give steam to the other, after which it finishes its own stroke and waits for its valve to be acted upon before it can renew its motion. This pause allows all the water-valves to seat quietly, and removes every thing like harshness of motion.

As one or the other of the steam-valves must always be open, there can be no dead point. The pump is therefore always ready to start when steam is admitted, and is managed by the simple opening and shutting of the throttle-valve.

The operation of the condensing-apparatus is as follows: Steam being admitted to the cylinders *K*, so as to set the pump in motion, a vacuum is formed in the condenser, the engine-cylinder, the connecting exhaust-pipe, and the injection-pipe. This causes the injection-water to enter through the injection-pipe attached at *B*, and spray-pipe *C*, into the condenser-cone *F*. The main engine being then started, the exhaust-steam enters through the exhaust-pipe at *A*, and, coming into contact with the cold water, is rapidly condensed. The velocity of the steam is communicated to the water, and the whole passes through the cone *F* into the pump *G* at a high velocity, carrying with it, in a thoroughly commingled condition, all the air or uncondensable vapor which enters the condenser with the steam. The mingled air and water are discharged by the pump through the valves and pipe at *J*, before sufficient time or space has been allowed for separation to occur.

It will be seen that the zone in which the condensation takes place is small, and the rapid effect is due only to the immense surface exposed by the spraying water. In case the water accumulates in the condenser-cone *F*, either by reason of an increased supply or by a sluggishness or even stoppage of the pump, as soon as the level of the water reaches the spray-pipe and the spray becomes submerged, the vast surface is reduced to a minimum, only a small annular ring being exposed to the steam from the main engine. The vacuum is immediately broken, and the exhaust-steam escapes by blowing through the injection-pipe and through the valves of the pump, and out the discharge-pipe at *J*, forcing the water ahead of it: consequently flooding does not occur.

These condensers have been constructed from those of a very small size up to those of enormous power. Two, which are probably the largest independent condensers in the world, are now applied to an engine of 8,000 horse-power, the injection-water of which amounts to 15,000 gallons a minute, or what is equivalent to about 20,000,000 gallons a day. Many of them are in use in connection with stationary steam-engines, and with marine engines on boats running in fresh water. The Worthington condenser is also used in connection with surface condensers on sea-going steamers, where it has a field of usefulness that is at once apparent to those who will but consider its functions. It performs the duty of two distinct pumps,—the air-pump and the circulating pump. It

produces a high vacuum, and causes a forced or positive movement of the cooling-water. By its use, derangement of the surface-condenser does not deprive the engine of the vacuum, as the inde-

pendent condenser, were located indiscriminately. The boilers and engines were not the most economical, but answered well for a time. Those companies that were fortunate enough to find themselves adjacent to water-supply, when they began to look around for better results, have not waited long to avail themselves of the increased output, or the corresponding saving in fuel, that is to be had by changing the engines from non-condensing to condensing.

Being perfectly adapted to high speed dynamo-engines, many electric light and power companies have found this independent condenser exceedingly valuable in connection with their steam-power. Twenty-five per cent saving in steam-consumption, and hence in the fuel burned, is frequently obtained. The increase in power often exceeds thirty per cent. In one of the above cases the

THE WORTHINGTON INDEPENDENT CONDENSER.

SECTIONAL VIEW OF THE WORTHINGTON INDEPENDENT CONDENSER.

pendent condenser can be used as a jet-condenser for the time being. The fact that one pump is dispensed with, should, in itself, commend the arrangement to the attention of engineers.

It is also a valuable adjunct to electric-lighting plants. Many of the plants that were erected during the early period of the history

gain is used to save steam, and in another to increase the output of power with same consumption of steam, and hence same fuel burned. There is a medium between these methods, and fuel can be saved and also power gained up to a sum total equal to the value of the twelve pounds per square inch made available by the

vacuum. The independent condenser is also used in connection with fire-pumps, mine-pumps, and water-works pumping-engines, as well as with vacuum pans and other evaporating apparatus. They are made by Henry R. Worthington of this city.

THE DEVELOPMENT OF THE POTTERY INDUSTRY OF THE UNITED STATES.

MR. WILLIAM C. DAY, in the recent issue of the "Report on the Mineral Resources of the United States," traces the history of the pottery industry, which has of late become of considerable importance.

The first pottery established in the United States was in New York City, in its earliest days, when under Dutch rule. It was situated near the North River, above the present Chambers Street, the locality being at that time well out of town, in the country. More than a century ago, perhaps, a small pottery was established in Trenton, N.J., by some Frenchmen. Here porcelain, similar to what is now known as French china, was made, and it is said that the goods were very creditable. This establishment existed for some years, but it attained no great importance. At Philadelphia there was a similar pottery venture, also making porcelain or china wares, which are well spoken of for quality. This enterprise was sustained for a number of years, but failed to reach a permanent existence.

There were other attempts to establish potteries in various parts of the country from time to time, and the only one which seems to have given the greatest concern to English manufacturers was one established in South Carolina. This was contemporary with the great Josiah Wedgwood, who has been called the father of the pottery industry in Great Britain, from the fact that he made great improvements in the quality of earthenware, which gave a very great impetus to the business in England. This South Carolina pottery proved quite alarming to Wedgwood, as he feared that it might become a dangerous competitor in supplying the earthenware markets of the colonies: he therefore petitioned Parliament that the manufacture of such goods be prohibited. He seemed to think, that, with the excellent materials found in South Carolina for making earthenware, the industry would become a successful one. His fears, however, proved groundless, as the unequal struggle was of short duration.

One or two pottery enterprises, inaugurated within the past forty years, making special articles of white crockery-ware rather than a general assortment, maintained their existence only, and cannot be termed successful.

The term "pottery industry," as understood at the present time, does not include the many little potteries scattered all over the United States, making stone-ware jugs, pie-plates, drain tile, yellow crockery, etc., and which employ from six to twenty men each. These little establishments made the cheapest and commonest class of pottery products, with which foreign competition was powerless. Owing to the very low-priced class of such wares, the expenses of their importation bore so large a proportion to their cost at the foreign potteries, that competition was out of the question. In fact, in many cases the crates in which the goods were packed, and the inland transportation charges, equalled the original cost of the goods themselves. The pottery industry, as now spoken of, had therefore practically no existence in the United States in 1861, the several hundreds of so-called potteries in this country which statistics show then existed being all of the class above referred to. The Morrill Tariff Bill, and the increase of duty from 24 to 35 per cent, and the subsequent increase to 40 per cent, did not act as inducements towards the establishment of any new enterprise. In 1863 the rapidly increasing premium on gold offered the necessary inducement, and several pottery enterprises were inaugurated. These manufactured at first the commonest class of crockery-ware for domestic uses; but as experience gave confidence, and the wares gradually found favor, better grades were made, until the standard of the china-ware used by the millions of American citizens, and manufactured in this country, is recognized as equal to that made anywhere. It is true that there are several potteries in the United States who make more or less of very fine art

pieces, which are forcing recognition on account of their superior excellence; but the stability of the pottery industry rests upon the fact that it supplies the wants of the people for fine and common crockery for domestic uses, of which we in this country manufacture about 60 per cent. The American potter does not claim to be the peer of his foreign competitor in art productions, but he does claim to equal any foreign manufacturer in the class of china which he produces for the American people. To-day the English potter is copying American shapes, designs, and styles of decorations. How different is this state of affairs from that which existed a few years ago, when the American potter depended upon foreign ideas for his shapes and designs! With the development of the manufacturing process, talent for designing shapes and patterns or styles of decoration has likewise progressed, until we have made our own American shapes and designs, which foreigners have been compelled to copy and adopt in order to find a market for their wares in the United States.

This country still takes about 40 per cent of the total crockery-ware exported by England. This is about the proportion that has been maintained for many years, thus showing that the American potter has increased his output in keeping with the increased consumption of the country.

In regard to the present prices of pottery, it may be said that the consumer can now obtain for two dollars and a half what in 1861 would have cost four dollars.

The pottery industry gives direct employment to about ten thousand people, to whom wages amounting annually to four million dollars are paid; this amount being nearly 50 per cent of the total value of the output of the potteries. In addition to these, there are many thousand more employed in the preparation of the materials for the potter's use, such as mining the clays, quartz, and felspar, and grinding and washing the materials. To these people nearly as much more in wages is paid; in fact, a careful estimate shows that 90 per cent of the cost of manufacturing pottery is paid for labor in one form or another.

The decorating branch of this industry is one of its most interesting features, and one in which great advances have been made in late years. It gives employment of a light, interesting, and elevating character to many young people, both male and female. The growth of this branch has been wonderful, and has made the demand for beautiful decoration, both simple and elaborate, very general, and far more wide-spread throughout the country than ever before. Formerly beautiful decoration was to be found only in costly French and English wares, and the consumption was consequently limited to the wealthiest classes: now beautiful decorated wares are found in almost any household, where they have been obtained at prices which would have been considered impossible a few years ago, and which have reduced very greatly the cost for French and English decorated products, and to a very great extent have enabled American decorated ware to supersede the foreign.

HEALTH MATTERS.

YELLOW-FEVER. — Dr. George M. Sternberg, U.S.A., has been relieved from duty at Baltimore, and is, by direction of the President, in pursuance of the authority contained in the provisions of the Act of Congress approved March 3, 1887, "making appropriations for sundry civil expenses of the government," etc., relating to the methods of preventing the spread of epidemic diseases, to proceed to the Island of Cuba for the purpose named in the letter of the President addressed to the secretary of war, April 17, 1888, and upon completion of this duty to return to his proper station and submit his report to the President. Dr. Sternberg is at the present time at the Hoagland Laboratory, Brooklyn, of which he is general director, engaged in making his preparations for his proposed trip to Cuba to pursue his investigation in yellow-fever. He expects to leave for Havana during the latter part of March.

LEGAL REGULATION OF MEDICAL PRACTICE. — The laws of West Virginia require that every physician in that State must have a certificate from the State Board of Health to entitle him to prac-

tise. An irregular practitioner attempted to evade this legal requirement, and was prosecuted. The case, being decided adverse to him, was finally carried to the Supreme Court of the United States on the ground that the act was invalid. This court sustained the lower courts in the following opinion: "The power of the State to provide for the general welfare of its people authorizes it to prescribe all such regulations as may be necessary to secure the people against the consequences of ignorance and incapacity as well as deception and fraud. One means to secure this end is the method adopted by the State of West Virginia. If the means adopted are appropriate to the calling or profession, and obtainable by reasonable study and application, no objection to their validity can be raised."

CONTAGIOUSNESS OF CONSUMPTION.—Mr. MacMullen, in the *Australasian Medical Gazette*, calls attention to the danger to which healthy travellers are subjected by consumptives. To illustrate this danger, he narrates a case in which a healthy man, on the voyage from London to Australia, was placed in the same stateroom with a consumptive in search of health. Now that consumption is regarded as a communicable disease, there is no longer excuse for this commingling of well and sick in such confined quarters as a ship's stateroom. Steps should be taken by the owners of steamships and other vessels to separate those who are so unfortunate as to have consumption, from those that are healthy, to the degree, at least, that the unsuspecting traveller would not be required to breathe the air impoverished and possibly infected by an invalid suffering from pulmonary consumption.

DOCTORS ADVERTISING.—The Board of Health of Illinois a few months ago revoked the license of H. G. Wildman, a physician, the chief charge being that he had overstepped the ethics of the profession by advertising his success and skill in newspapers. Dr. Wildman then appealed the case to Gov. Oglesby, and he rendered his opinion a few days since, reversing the decision of the Board of Health, and claiming that a physician should not be debarred from practice because he advertises what he can do and has done. Dr. Wildman expends over forty thousand dollars yearly in advertising in papers all over the Union, and several of the Illinois papers went on his bond in the action.

PUBLIC MEDICAL LIBRARIES.—In the proceedings at the reception given to Dr. Oliver Wendell Holmes, says the *New York Medical Record*, on the occasion of his presenting his library to the Boston Medical Library Association, Dr. R. M. Hodges, president of the association, gave some facts regarding the public medical libraries of this country. "First," he said, "in point of time, is the library of the Pennsylvania Hospital, founded in 1760; second, that of the College of Physicians in Philadelphia, founded in 1788; third, the New York Hospital Library, in 1796, etc. Of course, the library of the surgeon-general's office has surpassed in size all these, having a large annual appropriation and a magnificent librarian. Next in rank comes the library of the College of Physicians; next, that of the Academy of Physicians; and our library comes fourth in rank. After that come the Medical Department of the Public Library of Boston, and the New York Hospital Library. In other words, although the youngest of these seven libraries, ours has already passed three of them. We have nearly twenty thousand volumes."

DANGER IN THE POSTAGE-STAMP.—The *Sanitary News* calls attention to the fact that a postage-stamp may in various ways convey contagion. One of the simplest and most plausible is that in which a postage-stamp, partially attached to a letter to pay return postage, is sent by a person infected with some disease to another person. The disease is transferred, in the first place, to the adhesive stamp through the saliva, and in being attached to the letter by the receiver the poison may be transmitted to him in turn through the saliva. Another cause may be the infection of the stamp with disease germs. The stamp, having been exposed in a room where a diseased person lies, may become slightly moistened, and thus retain the germ. That this is true can be proved very simply by a microscopical examination. We often see a person holding change for a moment in the mouth, probably not knowing that investigation has shown that disease germs can be carried by

money. If one could see through what hands the money has passed, he would hesitate before using such a third hand. Silver money is as bad as paper money; but, while many would hesitate to hold a dirty bank-note in their mouth, they think that a silver piece, because bright, is apparently clean.

SANITARY PLUMBING.—In speaking of the effects of sanitary plumbing, the *Sanitary News* says, "Dr. A. R. Carter, of the health department of Baltimore, has published some interesting statistics in regard to the effects of sanitary plumbing. He says that during a period of fifty-four years, from 1830 to 1883 inclusive, there were in that city 12,197 deaths from scarlet-fever, being an average of 226. In the last of those years there were 334 deaths. But the city council then passed an ordinance regulating plumbing, and in the years since, there has been a remarkable decrease in the mortality from scarlet-fever. In 1884 there were 104 deaths; in 1885, 67; in 1886, 32; and in 1887, 36; making a yearly average of 60, but with a plain tendency to decrease. The yearly average of deaths from diphtheria has in the same way diminished from 469 to 234." This kind of reasoning is, in our judgment, very fallacious. If the diminution of diphtheria in Baltimore is to be attributed solely to the improvement in plumbing, why did not the same result take place in New York and Brooklyn, where the improvement in plumbing has been most marked since 1882? In that year in New York there were 1,009 deaths from diphtheria; in 1884, 1,090; 1885, 1,325; 1886, 1,727; 1887, 2,167. In Brooklyn in 1883, 409 deaths occurred from this disease; in 1884, 385; 1885, 519; 1886, 782; and in 1888, 984. So far as scarlet-fever is concerned, the statistics of Brooklyn show no such marked difference in the various years as could be attributed to the plumbing. Thus in 1883 there were 505 deaths from this disease; in 1884, 218; 1885, 363; 1886, 340; and in 1888, 475. In New York there was a notable decline from 2,066 deaths in 1882, to 744 in 1883, which could not be attributed to improvements in plumbing. Since that time the number of deaths has not been as high, but the diminution cannot, we think, be traced to the better plumbing. We do not wish to be understood as disbelieving in the value to life and health of good plumbing,—on the contrary, we regard it as one of the most important factors in the preservation of health,—but we do not think it the only factor, and believe it to be a mistake to attribute the reduction of contagious disease in any small series of years to a single cause.

ELECTRICAL NEWS.

Hertz's Researches on Electric Oscillations.¹

AFTER proving the existence of displacement currents in dielectrics, Hertz turned his attention to the propagation of waves in wires. To investigate this phenomenon, he used the apparatus shown in Fig. 9 (Fig. 11 in article). Here the primary circuit consisted of the two brass plates *AA'*, connected by a conducting wire in which was an air-space. The secondary used was either *B* or *C*, a rectangle and circle of wire respectively, the periods of which were equal to that of the primary circuit,—about .00000014 of a second. The conducting plate *P* was placed behind and close to *A*, and a wire was taken from it in the direction shown, passed through a window, and at a distance of 60 metres was buried in the ground. Now, when the induction-coil is working, and oscillations occur in the primary circuit, disturbances are caused in the circuit *Pnn*, because of the induction of *A* upon *P*; and the period of this disturbance is of course equal to that of the primary. If the wire *mn* were short, there would be danger of disturbances from reflected waves, but 60 metres was found to be a sufficient length to obviate this.

When electrical waves pass through the wire, we should find loops and nodes, as in any other form of oscillation. To test this, secondary circuits whose periods were approximately that of the primary were brought close to the wire, and were moved along it, the result being noticed at different distances. As the secondary passed along, points of maximum and minimum effect were observed at regular intervals. The results are interesting. In the first place, the distances of minimum effect were —0.2 metres,

¹ Continued from No. 314.

2.3 metres, 5.1 metres, and 8 metres; and in another experiment, —.1 metres, 2.8 metres, and 5.5 metres. The half wave-length, then, cannot be far from 2.8 metres, which would give, taking the period as .00000014 of a second, a velocity of propagation of 200,000 kilometres a second,—a result which lies between Fizeau and Gougnelle's values of 100,000 kilometres for iron and 180,000 kilometres for copper, and Siemens's results, which gave from 200,000 to 260,000 kilometres per second for the velocity in iron wire. Another important point is, that, if the copper wire be replaced by one of different metal, the nodal points remain fixed,—that is, the velocity does not change,—and the same is true when the diameter of the wire is changed. This result is striking,

FIG. 9.

especially as showing that at such short periods the magnetic properties of iron wire have very little effect on the phenomenon.

Now, it is evident that a secondary circuit, such as *B*, Fig. 9 (Fig. 11 in paper), is subjected to two actions,—the action of the current in *mm*, and the direct action of the primary. If we obtain for any position of *B* a certain result, due to the combined action, and if, keeping the direction the same, we shift *B* along the wire a distance corresponding to one wave-length, then, provided the direct disturbance travelled with the same velocity as that along the wire, we should have a result of the same character as at first: if the actions were primarily in the same direction, they would still be so; if they at first opposed, they would still oppose one another. If, however, the actions travelled with un-

FIG. 10.

equal velocities, they would change their relative directions as the secondary was shifted along the wire,—slowly if the velocities were nearly alike, faster if they differed considerably. This is the result which Hertz obtained; the change of sign taking place, when the observations were at a considerable distance from the primary, in a distance of 7.5 metres,—a result which would give for the velocity in air a value equal to that in the wire multiplied by the ratio of 7.5 to 7.5—2.8, or 320,000 kilometres per second. Considering the very rough methods of experiment, this agrees very well with the velocity of light, which is approximately 300,000 kilometres per second.

But in this experiment a very important fact was developed. While the change of sign took place in a distance of 7.5 metres at points considerably removed from the primary, yet near the primary the change of sign was in a much shorter distance. Now, we have seen that near the primary the electro-static effects are of the

greater importance, while at a distance from it the electro-dynamic actions can alone be considered. It would seem, then, that electro-static actions are propagated with greater velocity than electro-magnetic. It is hard to say from Hertz's results whether the velocity is infinite, since at a distance of 2.8 metres—the half-length of a wave on the wire—the magnetic effects are already of considerable importance. Still it seems fairly well proved that static and magnetic actions are propagated with different velocities, the latter being approximately that of light.

After this experiment, Hertz attempted to obtain evidences of the reflection of electro-magnetic waves from conducting surfaces. To do this, he placed the apparatus in a room whose dimensions were 15 metres in length, by 14 metres in width, by 6 metres high. There was a row of iron columns in the room, which cut off part of the available space, so that the width that could be utilized was reduced to 8.5 metres. All of the gas-fixtures having been removed, one wall of the room was prepared as a reflector by hanging on it a sheet of zinc, which was carefully attached to the gas-pipes and water-pipes. The primary circuit was arranged in a vertical position; the secondary was fitted so it could be moved into any position, this being usually accomplished by hand, although the body of the observer exerted a slight influence on the results. On placing the secondary in different positions between the primary circuit and the wall, results were obtained which are shown in Fig. 10 (Fig. 12 in article). With the secondary in the positions *I*, *II*, *III*, and *IV*, at distances from the wall shown by the scale, the strongest sparks were obtained when the air-space was in the position shown. At *V*, *VI*, and *VII* the same sparks occurred with the air-space at either side. This can be accounted for by supposing the waves to be those shown in the figure, the vibrations from the primary being reflected from the wall. Determining the length of the wave in this way, and assuming that they travel with the velocity of light, we obtain a period of .000000155 for the oscillations, instead of the .00000014 calculated from the dimensions of the circuit.

Such, in brief, are the most important of the results obtained by Hertz. He has developed a new experimental method, which in his own hands, and those of a number of physicists who are without doubt working now on the subject, will greatly extend our knowledge of what takes place in the vicinity of varying electric currents, and which will modify our views on the nature of electric actions. So far Hertz has shown that oscillations of short period can be practically obtained and experimented upon, and he has developed a method of investigation by means of a secondary circuit of a period equal to that of the vibration. He has shown, that, of the electro-static and electro-magnetic phenomena that accompany an oscillation, the former is of great importance near the oscillating current, but rapidly die away as the distance increases. He has shown that dielectrics have magnetic effects when placed near a conductor carrying an oscillating current, thus making more than probable Maxwell's hypothesis of "electric displacement." The velocity of a wave along a wire was determined, and from this the velocity of the electro-magnetic and electro-static waves in air were experimented upon. The former was found to be approximately that of light; the latter was much greater, but it was not possible to determine whether it was infinite. Lastly, electro-magnetic waves were reflected from a conducting surface, and their wave-length determined by the interference of the direct and reflected waves.

Hertz's work has put Maxwell's electro-magnetic theory of light on a firm basis, and has added experimental evidence to what was, after all, only an hypothesis.

ELECTRICITY AND LIGHT.—At a meeting of the Berlin Physical Society, Dec. 14, 1888, Professor von Helmholtz, the president, gave an account of a paper by Professor Hertz, which he had communicated the day before to the Berlin Academy. It contained a description of further experiments on electro-dynamic waves, and their analogy with waves of light. Weak induction discharges between small metallic cylinders with rounded ends were employed, and a similar apparatus for the detection of the electro-dynamic waves. The action was not propagated more than 2 or 3 metres through space; when it fell on a metallic surface, it was reflected, interference phenomena were observed, and from these the length

of half a wave was found to be 30 centimetres. When a metallic parabolic mirror, 1 metre across its opening, was placed behind the apparatus used to produce the discharge, the action was propagated to a distance of 8 metres; and the action was greatly increased when a second concave mirror was placed behind the receiving apparatus. When a conductor was interposed, the action ceased, while non-conductors allowed the waves to pass. By interposing perforated metallic screens, it was found that the waves are propagated in straight lines; the waves passed through a dry wooden partition. Polarization of the waves could be determined in several ways. When the receiver was placed at right angles to the apparatus producing the waves, no action between them could be detected, the vertically produced waves not being picked up by the horizontally placed receiver. When the two pieces of apparatus were placed parallel to each other, and a wooden cube, with a number of insulated metallic wire rings wrapped round it, was placed in the path of the electro-dynamic waves, it produced the same effect as does a tourmaline plate on polarized light. When the wires were vertical,—that is to say, parallel to the exciting apparatus,—the action was not propagated through the cube; but it was, on the other hand, when the wires were horizontal. When the receiver with its mirror was placed horizontally, so that it did not record any action as reaching it, and the wire arrangement described above was placed in the path of the waves, no change took place in the receiver when the wires on the cube were either vertical or horizontal; but the receiver was affected when the wires were placed at an angle of 45° . The laws of reflection of electro-dynamic waves at metallic surfaces were found to be the same as those for the reflection of light at plane mirrors. Finally, Professor Hertz has determined the refraction which the waves undergo in a prism made of pitch, and finds that the refractive index of this substance for electric waves is 1.68. Dr. Ritter demonstrated by experiments the action of the ultra-violet rays of light on electric discharges in accordance with the experiments of Hertz, Wiedemann, and Eberts.

LIGHT MOTORS FOR AERONAUTIC EXPERIMENTS.—M. Trouvé has constructed several small and extremely light motors of the Gramme and Siemens type, in order to carry out some aeronautic experiments. One of these motors, while only weighing about three ounces, is capable of developing .026 brake horse-power. All the parts of the machine are of aluminum with the exception of the magnets. This motor, which could be contained in a box 1.2 inches each way, is able to lift itself twenty-five yards a second by means of a wire and a fixed support. A one-horse-power motor constructed on the same lines would weigh barely eight pounds. When furnished with a light screw, and attached to the arm of a balance, the motor is able to lift its whole weight, when connected with a source of electric energy equal to forty watts. In order to facilitate his experiments, M. Trouvé places his motor at one end of a long lever capable of a vertical and horizontal movement about its centre, the electrical connections being made with the motor through the lever and its supports.

IMPORTANT PATENT DECISION.—In England the court of appeals has just handed down its decision reversing the finding of the lower court in the Edison incandescent lamp patent case. The case had been decided against Edison, principally on the ground of insufficient specification. This last decision upholds the Edison patents, and puts the Edison Company in England in the same position that it enjoys in Germany, where the patents have been uniformly upheld.

NOTES AND NEWS.

THE American Association for the Advancement of Science will meet at Toronto, Aug. 27 to Sept. 3; the first general session to be held on Aug. 28; the council meeting, on the 27th.

—The thirteenth anniversary of the Johns Hopkins University will be commemorated on Friday, Feb. 22, 1889. The public exercises of the day will be held in the Mount Vernon Place Methodist Episcopal Church at eleven o'clock. The public are invited to attend, and no tickets of admission will be required. The exercises in the church will close before one o'clock. The trustees,

faculty, alumni, students, and gentlemen personally invited, will assemble at the university at half-past ten o'clock, and proceed in a body to the church, where seats will be reserved for them. The alumni of the university will have a social gathering with a luncheon after the close of the exercises in the church. The physical laboratory will be thrown open from eight to ten o'clock in the evening to members of the university and their friends, and the chief instruments and pieces of apparatus will be shown to visitors. Professor Rowland will make an address to physicists in the hall of the physical laboratory at half past four o'clock, on "Modern Views with Respect to Electric Currents." Specials cards of admission will be required. Right Rev. Henry C. Potter, Bishop of New York, preached the annual sermon before the Christian Association of the university in St. Paul's Church (corner of Charles and Saratoga Streets) on Sunday, Feb. 17, at 8 P.M.: subject, "The Mastery and Mastering of Circumstances." All members of the university were invited to attend. The University Glee Club gave a concert in the Lyceum Theatre on Tuesday, Feb. 19, at 8 P.M.: tickets, fifty cents. The Athletic Association gave a gymnastic exhibition in the gymnasium on Thursday, Feb. 21, at 8 P.M. Tickets (fifty cents each) had to be obtained at the University Post-Office.

—At a meeting of the American Oriental Society, held at Philadelphia, October, 1888, Isaac H. Hall, Richard J. H. Gottheil, George F. Moore, Edward W. Hopkins, and Cyrus Adler were appointed a committee to obtain information respecting manuscripts that exist in America, written in the Oriental languages or connected with their study, with a view to the ultimate publication of a comprehensive catalogue of the same, in a worthy manner, and calculated to serve all the useful purposes of the Oriental catalogues of the great libraries of Europe. The manuscripts which are the subject of inquiry include all the ancient and modern languages and dialects of Asia, with those of Egypt and Ethiopia, whatever be the subject-matter of the manuscript, whatever be the character of the writing for elegance or negligence, whatever be the material upon which it is written, whatever be its state of preservation, or whatever be its length or size. The points of inquiry include the language of the manuscripts, if known; the style of writing, or the alphabet employed (as, if the manuscript be Arabic, whether in Cuñic or Neski, etc.; if Turkish, whether in Greek, Arabic, or Armenian letters, etc.), and the material upon which written; the size and binding (or absence of binding); number of leaves, and other external particulars of the manuscript; or, if a roll, its dimensions, and the number and dimensions of its columns (of fragments, papyrus, etc., the mere dimensions); the history of the manuscript, as far as known, and how it came into its present hands; if the manuscript is in a public library, both its present catalogue marks, and information respecting any former labels, library marks, or notes of ownership (the latter, of course, are desired if the manuscript is in private hands); also the date of the manuscript, if known.

—The field-work of the irrigation survey of the arid region of the United States is being vigorously prosecuted in Colorado and New Mexico, notwithstanding many disadvantages arising from cold and stormy weather. From Colorado, Mr. W. D. Johnson, in charge, reports the completion of the Pueblo and Huerfano sheet in fifty-foot contours, and on a scale of two miles to the inch, and considerable work done on the Apishapa and Juniata sheets, all being in the Arkansas valley. Mr. Johnson's parties, living in tents, have experienced temperatures below zero, and encountered twenty inches of snow; but such attention has been given to the men, that, beyond a few frost-bites, no trouble has been experienced in prosecuting work on every day not actually stormy. Work in New Mexico on the Lower Rio Grande has been commenced; Mr. R. Henry Phillips, in charge, reporting the arrival of his party at El Paso, and the occupancy of points connecting this work with the base-line measured near Fort Bliss in 1878 by the United States Engineers.

—Mr. Edwin Chadwick, the pioneer of sanitary reform in England, and indeed throughout the world, will, on the anniversary of his ninetieth birthday, March 2, be presented with a congratulatory

address by the Association of Public Sanitary Inspectors of England, of which body he is president.

— The third volume of "Studies from the Laboratory of Physiological Chemistry of the Sheffield Scientific School of Yale University" has just been published, under the editorship of Professor R. H. Chittenden, Ph.D. It contains the following subjects: "Some Experiments on the Physiological Action of Uranium Salts;" "Elastin and the Elastose Bodies;" "The Influence of Urethan, Paraldehyde, Antipyrin, and Antifebrin on Proteid Metabolism;" "The Influence of Several New Therapeutic Agents on Amyolytic and Proteolytic Action;" "Casesses, Caseine Dyspeptone, and Caseine Peptone;" "Some Experiments on the Influence of Arsenic and Antimony on Glycogenic Function and Fatty Degeneration of the Liver;" "The Nature and Chemical Composition of the Myosin of Muscle Tissue;" "Myosinoses, and the Relative Absorption of Nickel and Cobalt."

— The trustees of the Johns Hopkins Hospital have decided to formally open the hospital on May 1, and they have confided its organization to President Gilman of the university. It is said that for one year, at least, President Gilman will reside in the hospital, and exercise a close personal supervision over its executive management.

— Dr. John Call Dalton, one of the foremost physiologists of the world, and a writer of one of the best text-books on physiology, died in New York City on Feb. 12, at the age of sixty-four years.

— The French Association for the Advancement of Science will meet in Paris, Aug. 8-15; and the Congress of Geography and Ethnography will meet there Aug. 5-12. As the great exposition will also be open during August, extra inducements are offered to American scientists visiting Paris this summer.

— The fifth volume of the "Transactions of the American Institute of Electrical Engineers" is now in the hands of the binder. Including the index of current electrical literature, it makes a volume of 638 pages, and is fully indexed. Hereafter the monthly numbers will be paged consecutively, and should be carefully preserved for binding by all who desire to preserve the complete files, as they will not be revised and issued as an annual, as has been done this year in the case of Vol. V. Temporary binders for filing the numbers as received will be furnished by the secretary at seventy-five cents each.

— We have received from Hon. F. G. Adams, secretary, the "Sixth Biennial Report of the Kansas State Historical Society." The number of volumes in the society's library at the present time is as follows: namely, 9,971 bound volumes, 30,353 unbound volumes, 7,981 bound newspaper files and volumes of periodicals; in all, 48,305 volumes. Of the newspaper volumes, 5,757 are of Kansas. The list and tables which the report contains show that there is being made up by this society, for the use of the people of Kansas, a library of history and reference, remarkable in its growth, and still more remarkable in the character and value of the materials which it contains. They show that the growth of the library and collections has steadily continued from year to year during the thirteen years of the society's existence, and that in that time there have been placed on the library shelves more than forty-eight thousand volumes of books, newspaper files, and pamphlets; and, in addition to these, this and former reports show a collection of manuscripts, pictures, statuary, relics, and objects of historical illustration of every kind and description almost countless in number.

— The American Institute of Electrical Engineers (5 Beekman Street, New York), in addition to the letters from the Institution of Civil Engineers and the Society of Arts, has received one from the Institution of Electrical Engineers of London, to the effect that the president and council of that institution, having been informed by Mr. W. H. Preece, one of its past presidents, that many of the members of the American Institute will be visiting the Paris Universal Exhibition this year, and will probably also visit London, will take pleasure in welcoming those gentlemen, and in doing all that is in their power to render their visit to England agreeable and instructive. Communications of the same tenor, addressed to

the American societies of civil engineers, mechanical engineers, and mining engineers, led to the organization of an excursion, by which the members of those bodies were enabled to secure two special steamers, at the reduced rate of one hundred and ten dollars for the round trip to Liverpool. On account of the uncertainty as to proper accommodation in those steamers, and the early date of their departure (about June 1), the council of the American Institute does not deem it expedient for the electrical engineers to unite in the same arrangement, as the date fixed for the electrical conference at Paris (the latter part of August), together with the probability of the exhibition being in an incomplete condition, points to the desirability of fixing the date of departure about Aug. 1. Members who propose making the trip are, however, requested to notify the secretary as to the date of departure and return which would be most convenient for them; and, should it be found that a sufficient number agree approximately upon a date, an effort will be made to secure special rates. The regular excursion fare for first-class accommodations is one hundred and eighty dollars.

— In *The Microscope* for February, 1889, A. Clifford Mercer, M.D., describes a method of using with ease objectives of shortest working distance in the clinical study of bacteria. The working distance of homogeneous immersion objectives of short focus and great numerical aperture is little. In the clinical study of bacteria, sputa and other more or less fluid material are generally prepared on the under surface of cover-glasses, commonly, when not measured and assorted, so thick as to make examination with the above most suitable objectives impossible. To avoid this difficulty, Dr. Mercer dries and stains the material on the slide, drops homogeneous immersion fluid upon the preparation, and lowers the objective into the drop. Homogeneous fluid replaces both the balsam and the cover-glass with optical propriety. A twenty-fifth, which has been nearly useless over ordinary cover-glass preparations, is now used with gratifying freedom in manipulation over uncovered, but homogeneously immersed, slide preparations.

— The following is the list of the officers of the Kent Scientific Institute of Grand Rapids, Mich., for 1889: president, E. S. Holmes; vice-president, W. A. Gruson; recording secretary, C. W. Carman; corresponding secretary, E. S. Holmes; treasurer, C. A. Whittemore; director of the museum, W. A. Gruson; curator, C. W. Carman; librarian, E. L. Mosely; board of directors, Wright L. Coffinberry, W. A. Gruson, Samuel L. Fuller, E. S. Holmes, J. W. Jones, C. A. Whittemore; officers of the board, W. A. Gruson (chairman), E. S. Holmes (secretary), C. A. Whittemore (treasurer).

— The art schools of the Metropolitan Museum of Art have been established by the trustees of the Metropolitan Museum of Art, in order to furnish superior opportunities for thorough instruction in design, modelling, color, freehand, architectural, cabinet, and perspective drawing, chasing and hammered-metal work, carving in wood, painting on china, etc., especially to those who desire to acquire an artistic education applicable to industrial and commercial uses. Large, new, well lighted and ventilated rooms have been provided in a central position, with superior art material and instruction, and a liberal basis of admission. In order to offer all genuine students every facility in their work, a series of lectures have been added, the privilege of visiting the museum free of expense, prizes, diplomas, and opportunities for the sale of meritorious work; so that all may measure their progress by the degree of their industry and application. All payments are to be made in advance. Applicants for admission to the school must bring a letter of introduction from some resident of good standing. It is desirable that intending students should bring samples of their work to determine the degree of their proficiency. Those who follow the full course in each department receive diplomas upon passing a satisfactory examination at the close of the final term. The full courses are:—Drawing and painting, three seasons: 1st, Introductory class; 2d, "Antique" class; 3d, Life class. Sculpture, three seasons: 1st, In one of the drawing classes; 2d and 3d, In the modelling-room, with attendance at the anatomy lectures. Architecture, three seasons, the course to include architectural drawing, history and mathematics. It is intended that those who follow this course should be sufficiently advanced to pass the examinations of the

Paris Ecole des Beaux Arts. Diplomas will be issued to members of the normal, decoration, metal, wood-carving, and cabinet drawing-classes who have previously passed a season in one of the drawing-classes, and have shown satisfactory progress.

— A technical laboratory for special instruction in dyeing and bleaching, says *Nature*, has just been opened in connection with University College, Dundee. This technical portion of the chemical department consists of a completely fitted dye-house, a laboratory, and a museum for technical samples, more especially connected with the textile industries of the district. Practical instruction in the dye-house was begun by Professor Percy Frankland last week.

— It is well known that the aurora has a period of eleven years corresponding to that of terrestrial magnetism and of sunspots. It has recently been proved that the magnetical phenomena have a period of twenty-six days. This fact suggested to Mr. J. Lizar the plan of attempting to find a corresponding period in the frequency of the aurora. He subjected the hourly observations of the polar stations at Bossekop, Jan Mayen, and Fort Rae, in 1882-83, to an investigation, and found a very distinct period of this length, the maxima and minima of which corresponded exactly to those of the magnetic period. From this fact Mr. Lizar concludes that the connection between aurora and terrestrial magnetism is still closer than has been heretofore supposed.

— The tenth session of the International Congress of Anthropology and Prehistoric Archaeology will meet in Paris Aug. 19-26. The programme, subject to additions, is as follows: (1) "The Erosion and Filling-up of Valleys and the Filling-up of Caves in their Relation to the Antiquity of Man;" (2) "The Periodicity of Glacial Phenomena;" (3) "Art and Industry in Caves, and the Value of Paleontological and Archaeological Classification when applied to the Quaternary Epoch;" (4) "Chronological Relation between the Stone, Bronze, and Iron Ages;" (5) "Relations between the Civilizations of Hallstadt and the Other Danubian Stations and the Civilization of Mycenæ, Tirynthus, Issarlik, and the Caucasus;" (6) "A Critical Discussion of the Skulls and Quaternary Bones described in the Last Fifteen Years, with an Examination of the Ethnological Elements Characteristic of the Stone, Bronze, and Iron Ages in Central and Western Europe;" (7) "The Light which Ethnographical Survivals can throw on the Social State of the Early Populations of Central and Western Europe;" (8) "How far can Archaeological or Ethnographical Analogies be used to support Hypotheses in regard to Race Connections or Prehistoric Migrations?"

— The council of the Royal Meteorological Society, says *Nature*, have arranged to hold at 25 Great George Street, Westminster (by permission of the council of the Institution of Civil Engineers), on March 19-22 next, an exhibition of instruments connected with atmospheric physics invented during the last ten years, especially those used for actinic and solar radiation observations. The exhibition committee invite the co-operation of all who may be able and willing to send contributions. The committee will also be glad to show any new meteorological instruments or apparatus invented or first constructed since last March, as well as photographs and drawings possessing meteorological interest.

— *Germania*, a quarto fortnightly journal for the study of the German language and literature, edited by A. W. Spanhoofd, has just been published at Manchester, N.H.

— *Leif Erikson* is the title of a new journal to be published weekly at Chicago, under the editorial management of Miss Marie A. Brown, to prove, among other things, that the Norsemen discovered America, and that Columbus was an impostor.

— It is reported from north central Norway and Sweden, so says *Nature*, that wolves are very numerous this winter. They have re-appeared in districts where they have been unknown for many years.

— A new magazine for the blind, in raised Braille type, will shortly make its appearance in London under distinguished patronage. It will contain original articles and reprints of literary matter

of a high class, by the best authors of the day, politics being excluded.

— Brentanos have opened a branch at No. 430 Strand, London, which they intend to make "the headquarters of Americans in Europe, as is already the case with their house in Paris, by offering them all possible facilities for keeping fully informed of the doings of American authors and publishers."

— The German Government has granted, according to *Nature*, the sum of £27,500 to repair the building of the University of Berlin, and to erect new lecture-rooms, staircases, and corridors, and for the heating and lighting apparatus. The government has also given £36,500 to the Natural History Museum, besides £2,500 for books. A further sum of £1,000 is to be devoted to the purchase of physical apparatus and an anatomical cabinet.

— We have received a specimen copy of the *Interpreter*, an international review for universal language, edited, with assistance of numerous linguists of different nationalities, by Karl Lentre (Leipzig, Flossplatz 310). It appears monthly, and the subscription price is 50 cents half-yearly. The movement for a world-speech has now entered a new phase of evolution. Whereas formerly only persons of very limited capacity of judgment in linguistic matters have taken up Volapük, the idea of a national artificial speech is now gaining ground more and more among linguists, who examine Volapük and other similar attempts critically and scientifically. This procedure, however, does not suit the Volapükists, who opine that the faults and failings of a system do no harm if only the invention itself can be used. This standpoint is, however, quite untenable, for a language which cannot bear the test of scientific criticism is not likely to possess qualities insuring its lasting success. The *Interpreter*, published in English, German, and French side by side, is to be a central organ for scientific criticism in the department of world-speech, and will also furnish to those who have as yet kept aloof from this movement an opportunity to form a judgment as to the characteristics of Volapük, contrasted with those of a real world-speech gradually to be evolved. The articles in the first number are conceived in this sense. The *Interpreter* is likewise well-adapted, by the way, for the pursuance of studies in German or French. Specimen copies may be had of the publisher, in America, of E. G. Hethorn, New York, P. O. Box 2571.

— The following are from the table of contents of the March number of *The Chautauquan*: "Gossip about Greece," by J. P. Mahaffy of Dublin University; "Alcibiades," by Thomas D. Seymour of Yale University; "Greek Art," by Clarence Cook; "Color in the Animal World," by the Rev. J. G. Wood; "Industrial and Social Effects of the Sewing-Machine," by Ernest Ingersoll; "The Care of Criminals," by the Hon. Z. R. Brockway, general superintendent of New York State Reformatory; "The Commercial Relations of American Countries," by Professor A. D. Morse of Amherst College; "Embezzlers and Defaulters," by John Habberton; "The Italians in the United States," by C. L. Speranza of Columbia College; "The Gladstone Fortune," by C. DeVarigny; "Water-Supply for Small Towns," by John S. Billings, M.D., surgeon United States Army.

— We learn from *Nature* that Professor Fitzgerald and Mr. Trouton have been conducting experiments confirmatory of Hertz's magnificent work. Lately, using parabolic mirrors after the manner Hertz recently described, they have observed the phenomenon of the polarization of radiations by reflection from a wall three feet thick. They observed long ago, and exhibited publicly at the opening meeting of the Experimental Science Association last November, that stone walls are quite transparent to these radiations, as they should be, and consequently should not reflect radiations polarized perpendicularly to the plane of incidence at a certain incidence. This is what has been observed, and it has been decided that the plane of polarization is the plane of the magnetic disturbance. They next tried reflection from sheets of glass, and obtained no results; but, as Mr. Joly suggested, the experimenters were practically observing the black spot in Newton's rings, for the sheet of glass was much thinner than a wave-length, which is about thirty centimetres. Some rough observations at various incidences from the wall seem to show interference at some and not at other incidences due to the same cause as Newton's rings.

SCIENCE:

A WEEKLY NEWSPAPER OF ALL THE ARTS AND SCIENCES.

PUBLISHED BY

N. D. C. HODGES,

47 LAFAYETTE PLACE, NEW YORK.

[Entered at New York Post-Office as second-class mail-matter.]

SUBSCRIPTIONS.—United States and Canada.....	\$3.50 a year.

United States at the Paris Exhibition.			

THE UNITED STATES will make a creditable display at the Paris Exhibition. And this is as it should be; for, although nominally a universal exposition, it will be practically a display of the products of republics. The monarchies of Europe will be represented only by private exhibits, while the republics of North and South America have rallied in force. The United States Department of Agriculture will make a splendid showing. Secretary Colman has placed the undertaking in the hands of Professor C. V. Riley, the famous entomologist, an energetic organizer as well as a careful and enterprising scientific observer; and Professor Riley has already sent forward three car-loads of products, which are on the way to France in charge of Mr. F. T. Bickford, an assistant. The bulk of shipments are nearly through with, and the perishable staples will follow during the next month. Congress appropriated \$250,000 to aid exhibitors, and Secretary Colman's quota of this will insure the best illustration that the agricultura. resources of this country have ever had on the continent of Europe. Various branches will be represented as follows: fruit, Professor VanDeman and Professor George Hussman; grain, George N. Hill, St. Paul, Minn.; cotton and fibres, Col. James A. Benford, Duck Hill, Miss., and Charles R. Dodge, Boston; tobacco and peanuts, Alexander McDonald, Va.; agricultural education and

experimental stations, W. O. Atwater, Department of Agriculture; vegetables, including hops, M. G. Kern, St. Louis; entomology, including apiculture and silk-culture, C. V. Riley, N. W. McLean of Hinsdale, Ill., and Philip Walker, Department of Agriculture; sorghum and other sugar-plants, H. W. Wiley, Department of Agriculture; forestry, B. Fernow, Department of Agriculture, and M. G. Kern of St. Louis; grasses and forage-plants, George Vasey, Department of Agriculture; meat products, Dr. de Salmon, Department of Agriculture. All articles for exhibition will be forwarded free from New York, and no charge will be made for space in Paris. Professor Riley has put forth unusual exertions to get the exhibit on the road, and he looks forward with much enthusiasm to the result. He will not leave for Paris till the first week in April.

PHOTOGRAPHIC MAP OF THE NORMAL SOLAR SPECTRUM.

A NEW and greatly improved edition of this map, made by Professor H. A. Rowland, extending from the extreme ultra violet down to and including B to wave-length 6950, is now ready. The old map, published in 1886, was made by means of a grating ruled on the old dividing-engine, which was originally intended for only small gratings, and at a time when Professor Rowland's knowledge of photography was limited. Furthermore, it was not printed in a sufficiently careful manner; and the negatives, which were originally none too good, soon became broken or defaced, so that many of the prints, especially the later ones, were not satisfactory.

The whole work has now been gone over again. A new dividing-engine to rule large gratings has been constructed, and has proved to be superior in every way to the old one, although the old one is almost equal to it for small-size gratings. It has been placed in the vault of the new physical laboratory, where an almost constant temperature is maintained. Several concave gratings of 6 inches diameter and $2\frac{1}{4}$ feet radius have been ruled with 10,000 or 20,000 lines to the inch, giving definition hitherto undreamed of. These have been mounted in the best possible manner. The laboratory contains rooms for developing, making emulsions and dry plates, complete enlarging apparatus, and, indeed, every facility for photographic work on the spectrum of the sun; and a large steam-engine, a variety of dynamos, continuous and alternating current, with Ruhmkorff coils of all kinds, one of which latter will melt down iron wire larger than one-sixteenth of an inch in diameter in the secondary circuit, give means of future investigation on the spectrum of the elements. Professor Rowland has devoted years to the making of dry plates, simple and orthochromatic, and is thus better prepared than before for the work of making the map. He has also revised his list of standard wave-lengths, and extended them into the ultra violet, and has placed the scale upon the photographs with greater care than before. The printing is carried on in Baltimore, where it is under the immediate supervision of Professor Rowland.

The negatives have been made on thick French plate glass, and the prints are much more artistic than the old ones. The definition is not only much finer throughout, but the prints are much more uniform, and have fewer spots.

The process of making this map is the same as that used for the old one, and is based on the property of the concave grating as discovered by Professor Rowland: this property is, that the spectrum, as photographed in any given order, is normal, and of the same scale throughout. The focus remains automatically adjusted, so that one has only to move the instrument to the part of the spectrum required, absorb the overlying spectra, and put in the photographic plate. The negatives enlarged have been selected from many hundreds taken from different gratings, though three gratings were finally selected for the work. The negatives from any given order of spectrum are measured from one standard line to another on a dividing-engine, so that the constant of the dividing-engine is known. The scale is then made by ruling on a piece of French plate glass having a coating of blackened collodio-chloride. The negatives are then clamped to the scale firmly, after being adjusted into position by the standards. They are then put in the enlarging apparatus, and the whole enlarged from two and a half to possibly

four times, so as to make the scale of the map about three times, that of Angström's map. The positives thus made are then figured, and negatives made from them by contact.

In the negatives so far examined, the scale has been placed within less than $\frac{1}{10}$ Angström division, or $\frac{1}{100000}$ wave-length of its true position.

As to the definition, much is lost in the enlargement, not so much from want of definition in the enlarging lens, a 25 by 21 inch Dallmeyer, rapid rectilinear, as from the radical defect of photographic processes; for, when one brings out the fine doubles in which the streak of light in the centre is very faint, he loses many of the fainter lines. The original negatives show E, and even finer lines like that at wave-lengths 5276.1 and 5914.3, plainly double, but there is little hope of showing this on the map.

The atmospheric line just outside of one of the D lines also nearly merges into it, although in the original negative it is widely separated from it.

However, there are few instruments which will show more of the spectrum than can be found on the map, even below the D line, where cyanine and chlorophyl plates had to be used, for the first line in B is shown widely triple. Above, and including the D line, the definition rapidly improves, and a low-power magnifier must be used to bring out the full definition. However, from wave-lengths 5300 to 3800 the superiority over the old edition is not so marked as above and below this. In the ultra violet above H there is an immense improvement in the new, both in definition and in the quality of the photograph.

As to comparison with other maps of the spectrum made by measurement and drawing, it may be said that no comparison is possible. The photograph is the work of the sunlight itself, and the user of this map has the solar spectrum itself before him, and not a distorted drawing full of errors of wave-length and of intensity. The superiority is so great that there is no possibility for comparison.

The following is a list of the plates, each 3 by 2 feet, containing two strips of the spectrum: *a* includes from wave-length (?) to 3350; *b*, from wave-length 3270 to 3730; *c*, from wave-length 3670 to 4130; *d*, from wave-length 4050 to 4550; *e*, from wave-length 4450 to 4950; *f*, from wave-length 4850 to 5350; *g*, from wave-length 5250 to 5750; *h*, from wave-length 5650 to 6150; *i*, from wave-length 6050 to 6550; *j*, from wave-length 6450 to 6950.

Negatives *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*, *j*, are now ready, although that for *i* is too irregular to be entirely satisfactory, and it may be replaced. The plate *a* to the extremity of the solar spectrum will be attempted this summer, but may cause much trouble and delay, and will be sold as an extra plate. The prints are on heavy albumen paper mounted on cloth.

The cost of printing has been so much increased that the prices for this new series will be greater than for the old one, but scarcely more than covers the cost of the printing.

The plates will be delivered in Baltimore or New York, or will be sent by express or mail, securely packed, at the charge and risk of the purchaser, at the following net prices: set of nine plates, wave-length 3270 to 6950, \$18; single plates, \$2.50. Should any extra plates continuing the spectrum in either direction be published, subscribers can have them at \$2 each. Subscribers to the old edition will have the preference in the delivery of the new one, and a reduction of 10 per cent in the price. The three plates *h*, *i*, *j*, to complete their set, will be furnished for \$6. They are advised to take *g* also, as the old map of that region was bad. The four, *g*, *h*, *i*, *j*, will be furnished to them for \$8.

Two plates, each 3 by 2 feet, suitable for framing and hanging on the wall, have been made of the B and D lines. The latter are 3 inches apart, and the former has an extent of about 24 inches. Enlargements of some of the carbon bands from the arc electric light have also been made. They show the wonderful structure of these bands, each containing many hundred lines, each one of which is a close double, or, in some cases, a triple. These plates will be sold for \$2.25 unmounted, or \$2.50 mounted on cloth. No plate will be given away or sent in exchange. Remittances may be made by draft or money-order. All subscriptions and orders should be sent, and remittances made, to the Publication Agency of the Johns Hopkins University, Baltimore, Md.

THE EARTHQUAKE OF LIGURIA, FEB. 23, 1887.

MESSRS. T. TARAMELLI and G. Mercalli have made an exhaustive report on the earthquake of Liguria in February, 1887, to the Italian Department of the Interior. A geological and an historical chapter form the introduction, which is followed by an account of the results of the authors' studies and inquiries. They visited all localities that were severely damaged by the shocks, while information on others, which they were not able to visit, was collected by means of circulars of inquiry. Thus exhaustive reports on the character of the earthquake were obtained from over eleven hundred localities. This abundant material, arranged and discussed systematically, forms the basis and the main part of the report. The results of this discussion are summarized by the *Naturwissenschaftliche Rundschau* as follows:—

Many insignificant, preparatory shocks preceded the Ligurian earthquakes of 1752 and 1854, as well as that of Feb. 23, 1887. In the night from Feb. 22 to Feb. 23, four light shocks were felt over exactly the same territory that was visited by the severe shocks of the following day. Evidently the seismic centre was in full activity that night; but there are only four indications, as no seismic instruments and observers exist on the Riviera di Ponente. A little while before the earthquake began, the sea was observed to be exceptionally quiet. A few observers claim to have seen unusual lights in the atmosphere. In the regions which suffered most severely, animals were observed to be restless. In a very few places a change of springs was observed. Thermometer and barometer were not influenced by the shocks.

The principal shock was observed in a circular area covering about 568,000 square kilometres. Its southern limit is Rome and Mount Ferru in Sardinia. Eastward it extends to Pordenone, westward to Perpignan, and northward to Dijon and Basle. The shocks spread with greater force northward to France and western Switzerland, than southward on the Italian peninsula. According to the intensity of the phenomena, the authors distinguish four zones; the central region, in which the most formidable destruction took place, forming a zone a hundred kilometres in width along the coast from Mentone to Albissola. It embraces a narrow coast strip, because the seismic centre was situated in the sea, and because the old crystalline rocks of the Ligurian Apennines reflected the seismic waves. The next zone is called by the investigators the "almost destructive" one. It extends to the hills of Piedmont. Very strong shocks were felt in the third zone, which extends from the second principally north-westward, including Turin and the low-lying Canavese, where the shocks seem to have been increased in violence by waves reflected from the gneissic mass of the Grand Paradiso. The last zone embraces those places in which the earthquake was felt, but did not do any damage.

In the whole territory where the earthquake was strongly felt, the first shock lasted thirty seconds, and consisted of two shocks almost immediately following one another. Each of these shocks caused first a subsultory, then an undulating motion. In no place, not even in those where the shocks were most destructive, was the movement vertical. Therefore the resultant of both shocks was much influenced by local causes, and neighboring places show great differences in the direction of the shocks. The second shock was the stronger one, causing particularly a strong subsultory movement. Only in Nice and other places in France the first shock was the strongest. The second part of the shock was everywhere complicated by the resultant action of its combination with the first shock. This accounts for the fact that the second shock frequently left the impression of a rotatory movement. In many places, for instance in Mentone, objects lying on the ground have been turned round. In places lying at greater distances from the central point, the vertical component decreased rapidly, but all the other peculiarities of the shock remained. In the outlying zone the slowness and regularity of motion of the shock were remarkable, which caused pendulums three feet and more in length to swing.

At various places the horizontal velocity caused by the shock was determined by observations, and by objects thrown some distance. At Oneglia the force was large enough to give a portion of a sill, weighing about five thousand pounds, an initial velocity of thirty-one feet. This horizontal force decreased with increasing distance

from the centre. At Taggia it was twelve feet; at Nice, fifteen feet.

In many places of the region where the earthquake displayed its greatest power, some observers claim to have heard a noise preceding the motion. To some it seemed to be similar to the rattling of a train; but it is more generally compared to the howling of a hurricane, or to the rattling of a cart rolling over a stone pavement, or to distant thunder. Even in the third zone there are numerous places in which the noise was heard before or during the shock. In the fourth zone it was noted in very few places. In several places in the province of Porto Maurizio a subterranean noise was all that was observed; it was not followed by any movement.

Great care was given to the determination of the direction of the first shock. The methods applied were to inquire into movements of lamps and other hanging objects, the stopping of pendulum clocks, the removing or falling of objects, and the destruction of buildings. This part of the investigation showed, that in the whole region of the Ligurian Apennines, which was shaken most violently, all directions were equally frequent. This fact suggests the existence of an elongated epicentre parallel to the Ligurian coast. East of the meridian of Oneglia, directions between east-north-east to west-south-west and north-east to south-west prevailed. West of this meridian the greater number of waves were in the directions from east to west and from south east to north-west. In many places the direction of the movements changed once or twice during the first shock. Thus movements resulting directly from the shock, and secondary waves, could readily be distinguished. In many cases, among the various directions, two were prevalent which were vertical on one another.

A remarkable phenomenon was observed in the valley of Padua. The direction pointing towards the centre of the disturbance existed only during the latter part of the shock. In the beginning the crystalline rocks of the West Alps, which were shaken a few moments before the neighboring recent deposits, deflected the waves towards the arc of the valley of Padua, giving them an east and west direction.

If all important directions of shocks are marked on a map of western Liguria, they will be seen to converge in the sea between Oneglia and St. Remo about fifteen or twenty-five kilometres south of the coast. Therefore this is the probable place of the epicentre. The same place results from a study of the isoseismic lines which are concentric to a point twenty kilometres south of Porto Maurizio. A secondary centre seems to have been in the sea south of Nice.

A comparison of the most trustworthy reports shows that the Ligurian coast between Nice and Laona was struck by the great shock at 6.20 A.M.: therefore the shock must have reached the epicentre a little before this time, probably at 6.19 A.M. If this movement is considered the beginning of the shock, and the time of the disturbances observed at other places is compared to it, it appears that the velocity of transmission was not equal in all directions. It was greater to the west, being 4,762 feet in the direction of Marseilles and Nice, and only 1,916 feet in that of Genoa. This difference is probably not real, as the first shock of Nice seems to have originated at a secondary epicentre south of Nice, the existence of which was known through the earthquakes of 1564 and 1752.

Only in a few places was it possible to ascertain the vertical angle of the shock with any degree of exactness; but the value of 40° seems to be well assured by observations between St. Remo and Albenga. Based on these observations, and on the fact that this angle decreased with increasing distance from the epicentre, slower than it did in the great Andalusian earthquake of Dec. 25, 1884, the seat of the centre was found to be at a depth of eighteen kilometres, while that of the secondary centre south of Nice was somewhat less. It seems probable that the shocks preceding and following the most violent one also proceeded from the main centre, but that the first originated in a greater, the later in a less depth. The centre seems to have approached the surface during the seismic phenomena.

The violent shock was felt at sea between Corsica and the western Riviera by several vessels, which were shaken in all directions, the impression being that they had struck a rock. Almost everywhere on the Riviera the sea fell a little at the moment of the first

shock, and suddenly returned to its former level, without the destructive waves which have followed other earthquakes. Some observers maintain that the falling continued several days after the earthquake, while at Laona and Porto Maurizio a change of level is said to have taken place. No rise is said to have followed the first fall. At Nice, St. Remo, and Savona dead fish were collected after the earthquake. According to Bellotti, all of them were deep-sea fish: therefore it cannot be doubted that violent shocks occurred in considerable depths near the coast of Liguria. This confirms the opinion that the centre must have been under the sea.

The earthquake did not cause any important changes in the topography of the affected region, and all of them must be considered dynamical effects of the tremors upon the surface strata which were broken or slightly moved. None of the resulting changes are connected with the prime cause of the earthquake. No atmospherical phenomena proving the presence of an extraordinary amount of atmospherical electricity were observed. In this respect the Riviera earthquake differed from that of Andalusia.

About nine minutes after the first shock a second one followed, violent and long; then at 8.53 A.M. (Rome time) a third one, short, but almost as violent as the first, and very destructive in its effects. Both these shocks were felt slightly in the whole region disturbed by the first one. In the central zone about twenty-two shocks more were felt in course of the 23d and in the following night. Only one, at 2.20 P.M., was strong. After the 23d the number of shocks decreased; but they continued until March 11, when the most violent shock since the first three was felt. At Savona, between Feb. 23 and March 11, about fifty distinct shocks were felt. Only the shocks of Feb. 23 were destructive. Six hundred and forty persons were killed, and about as many wounded. The damage in the province of Porto Maurizio is estimated at \$2,600,000; in the environs of Albenga and Savona, at \$1,700,000. No detailed estimates are available from the French districts.

NATURE AND ORIGIN OF PHOSPHATE OF LIME.¹

THE circumstances which have led to the preparation of the subjoined report on mineral phosphates are as follows: viz., in 1870 the present writer was employed by the superintendent of the Coast Survey, the late Benjamin Peirce, to examine the phosphate beds of South Carolina with a view to determining the limits of that field; it was also deemed desirable to ascertain, if possible, the conditions which led to the formation of the deposits.

It was at that time the intention of Professor Peirce to have the geology of the belt of country within the limits of the Coast Survey maps carefully determined, so that they might be shaped in a way that would better serve the commercial interests of the country, and also have a greater scientific value. After a time it appeared that there were legal difficulties in the way of publishing these studies in the reports of the Coast Survey, and this work was suspended. It was the hope of Professor Peirce to secure a modification of the law; but before this was accomplished, he retired from the post of superintendent, and his successor deemed it best to abandon the project. During the two years in which I was engaged in this work on the geology of the coast line, I became very much interested in the problems connected with the origin and distribution of phosphatic deposits. From 1873 to 1880, while employed as State geologist of Kentucky, I had a chance to see a good deal of the somewhat phosphatic limestones of the Cambro-Silurian sections, — a set of beds which, by their decay, have given great fertility to the soils that lie upon them. The researches of Dr. Robert Peter, the chemist of that survey, made it plain that the phosphatic contents of the soils are among the first materials to be exhausted by the careless tillage which characterizes our American agriculture, and that they are the most costly to restore to the soil.

Extending the general inquiry to the grain-producing districts which lie to the north and west of Kentucky, it became evident that all those States which are now the granary of this country, and the chief source of supply for European markets as well, are rapidly exhausting their soils, and will soon be in grave need of

¹ Portion of an introduction, by N. S. Shaler, to a forthcoming bulletin of the United States Geological Survey, prepared by R. A. F. Penrose, jun.

phosphatic manures. The importance of such manures has so far been well recognized only by the cotton-growers of this country, yet it is evident that in a short time this class of fertilizers will be equally in demand for all forms of grain-crops.

These considerations have led me to the conclusion that the geological history of phosphatic deposits should receive more deliberate attention than has yet been given to it.

When I began my work in the United States Geological Survey, I asked permission of the director to continue my studies on phosphatic deposits. There was at the time no money available for these studies: it was therefore necessary that they should be carried on without other expense to the survey than that involved in the small share of my time which could be given to the supervision of the work. It was my good fortune, however, to find in one of my students of geology, Dr. R. A. F. Penrose, jun., a person who has been willing, at his own cost, to undertake a preliminary study of the whole field as far as our knowledge extends, and thus to prepare the problems concerning American phosphate deposits for detailed inquiry. This work he has pursued with great intelligence and energy during the two years in which he has been engaged in it. In this task he has examined all the known phosphate deposits of the United States and Canada, and has made a careful inquiry into the literature of the subject, as is shown by the extended bibliography which is appended to his report.

The object of this work being to make a necessary preparation for the further study of American phosphatic deposits, Dr. Penrose's studies were not designed to be encyclopedic in their scope, but rather to afford a synopsis of what is known of the deposits in this and other countries. So little is yet generally known of the several conditions under which these deposits may occur, that it would be very blind work to search for them in this country without a careful endeavor to bring together the experience which has been gained in other countries. It will be evident to the reader of Dr. Penrose's report that the workable deposits of phosphates are found in a greater variety of circumstances than those which contain most mineral substances that have an economic value. It is not likely that we have as yet exhausted the inquiry into the modes of occurrence of this substance; but this synopsis of the experience in this and other countries, which is much more extensive than any other which has been published, will, I believe, serve as a guide to the further search for sources of supplies of phosphatic manures. It will also be evident to the reader that the conditions of occurrence of these deposits in Europe make it plain that the search for them in this country may advantageously be directed to many districts in which they have not as yet been found.

So far, the vein deposits of apatite, such as those which are so abundant north of the St. Lawrence, have not been found in workable quantities within the limits of the United States, though the general geological conditions of the Laurentian area exist in the Adirondack district and in the southern parts of the Appalachian system, as well as in several districts of the Rocky Mountains. It would be remarkable if extensive deposits of this nature, so common in Canada and in the equivalent rocks of northern and southern Europe, should not be found at many points in our American Archæan formations. It is on this account that so much space in this report is given to the description and illustration of the Canadian apatite deposits. So, too, we may hope to find in the ancient rocks of this country deposits analogous to the great Logrosan and Caceres veins in the province of Estremadura, Spain.

The cretaceous deposits of Belgium (which at the present time are, next after the phosphate beds of South Carolina, the most productive in the world) present a type of beds the like of which have not as yet been discovered in the United States, though deposits of the same age, formed under about the same conditions, abound in this country. It is not to be expected that phosphatic deposits will exactly repeat themselves in strata of the same age in widely separated regions; yet it is clear, from the summary account of the geological distribution of these phosphates in Europe and North America, that in the case of these, as well as in that of other substances of value in the arts, there are certain guiding principles which we may base on the stratigraphy of the deposits to aid our search. The known workable deposits of a phosphatic nature are limited to certain portions of the geological section. Beginning at

the surface, the deposits now forming these zones are, in descending order, as follows:—

(1) Superficial deposits, including (*a*) those formed in the manner of guanos; (*b*) the deposits formed in the bottoms of fresh-water swamps, sometimes in connection with deposits of bog iron ore (hematite); and (*c*) deposits which are the result of the long-continued decay of rocks containing a small portion of lime phosphate intermingled with lime carbonate, as, for instance, the deposits of North Carolina. This superficial group of deposits has no other common feature save that they are on the surface, and are due to causes now or recently in action.

(2) Deposits of the tertiary and upper cretaceous. These deposits are generally the result of re-actions which took place on ancient land surfaces, the phosphatic matter being such as formed in swamp beds or in ablation deposits like those of the Carolinas or of eastern England. Below the level of the cretaceous no important deposits of phosphate have been found in the vast section of rocks which lies between that era and the Devonian horizons.

(3) In the horizons below the level of the upper Silurian, bedded rock phosphates and apatite deposits occur. These infra-Devonian bedded rock phosphates seem to have derived their phosphatic matter from the animals, brachiopods, and small crustaceans, which separated that substance from the sea insects or other food which the old oceans afforded them. These phosphate-bearing invertebrates appear to have been particularly abundant in the early paleozoic seas.

(4) Below the level of the Silurian the phosphatic deposits which have been worked probably belong altogether to the class of apatites or crystallized lime phosphates, and are probably all new deposits. They evidently occur through a large part of the Laurentian section, though, so far, the known deposits of economic importance are possibly limited to one portion of that vast series of rocks.

The apparent absence of phosphatic deposits of economic importance in the section between the Devonian and the cretaceous is remarkable. It is possible that it may be due to our lack of knowledge as to the chemical character of the deposits in those parts of the earth's crust. It is more likely, however, that such deposits do not there exist, owing to the fact that the invertebrate species of animals which secrete phosphatic matter in their skeletons became relatively less abundant in the middle portion of the geological section; while the vertebrate species, the birds which accumulate guanos, and the fishes which afford an abundance of bones and teeth to littoral deposits, as well as the mammalia whose skeletons occasionally form a considerable element in the later deposits, did not begin to contribute phosphatic matter to the rocks until comparatively modern times.

The absence of phosphatic deposits in the upper paleozoic and lower mesozoic strata is well shown by the fact, that, while in the carboniferous and the triassic beds there are abundant land surfaces which have been carefully explored, no phosphatic deposits of economic importance have been found in them; while on the relatively very limited areas of the tertiary and cretaceous formations, where old land areas have been explored, a large number of deposits of beds of nodular phosphate have been found.

From the facts set forth in Mr. Penrose's report and the unpublished results of certain studies on swamps, we may draw certain general conclusions as to the best method of prosecuting the search for unknown deposits of American phosphates. These conclusions are essentially as follows:—

First, as regards the superficial and recently formed deposits of phosphates. We are driven to the conclusion that this class of deposits may reasonably be sought for wherever soft calcareous beds containing a certain amount of lime phosphate have been subjected to long-continued leaching by waters containing the share of carbonic-acid gas which belongs to all rain-water after it has passed through the mat of decayed vegetation. As long ago as 1870 I became convinced that it was to the leaching-out of the carbonate of lime by the carbonated water of the soil bed that we owe in the main the concentration of the nodular phosphates of South Carolina.¹ Although it is still necessary to explain many of the details of this process to adapt it to the peculiar circumstances of particu-

¹ See Proceedings of the Boston Society of Natural History, xiii., 1871, p. 222.

lar deposits, it seems to me that it is the key to the most common forms of superficial accumulations of nodular phosphates. In an admirable description of the phosphate beds in the neighborhood of Mons, in Belgium, by Mr. F. L. Cornet,¹ that distinguished author has independently propounded this simple hypothesis, and several other writers on the subject have apprehended the importance of this leaching action.

It is evidently essential to this process of concentration that the surface of the deposits which are leaching away should have been preserved from the action of mechanical erosion, which would have prevented the formation of phosphatic concentrates.

Inquiry into the conditions of the swamp deposits of this country has satisfied me that beneath the surface of many of our fresh-water marshes, and probably in a lesser degree beneath the marine deposits of the same nature, there is a more or less important concentration of lime phosphates constantly going on. The effect of this action is seen in the remarkable fitness of these fresh-water swamp soils for the production of grain-crops. For instance: in the case of the Dismal Swamp district, in Virginia and North Carolina, we find that the soils on which the swamp deposit rests are extremely barren, while in the mud that has accumulated beneath the swamp we have a rich store of phosphates, potash, and soda, which causes the soil of these swamps to be extremely well suited to grain-tillage as soon as it is drained. In a similar way, in the swamps of New England and Elsewhere, we find the bog iron ores which are frequently accumulated in their bottoms very rich in phosphatic matter. The evidence is not yet complete that this phosphatic material becomes aggregated into nodules in the swamp muds, but the number of cases in which nodules have been found in this position makes it quite likely that the nodulation of the material may go on in that position. The present condition of the inquiry goes, in a word, to show that wherever we have a region long overlaid by swampy matter we may expect a certain concentration of lime phosphates in the lower part of the marsh deposit. Wherever the swamp area lies upon somewhat phosphatic marls which have been slowly washed away by the downward leaching of the waters charged with the acids arising from decayed vegetation, or where the swamp deposits, even when not resting on such marls, are in a position to receive the waste from beds containing phosphates, we may expect to find a considerable concentration of phosphatic matter in the swamp bed. By the erosion of these swamps we may have the nodules of phosphate concentrated in beds such as occupy the estuaries of the rivers near Charleston, S.C.

The area of swamp lands which fulfil these conditions is very large. They exist in numerous areas in more than half the so-called Southern States. At present it can only be said that they afford the conditions which, so far as the theory goes, should lead to the accumulation of phosphatic deposits of greater or less importance. It will be a simple matter to explain these deposits, though it is a task requiring a patient study of a large field. Although it is likely that the phosphatic materials will be found aggregated into nodules at many points in this area, it will not be safe to assume that they will be found in the same form as those which occur about Charleston, S.C. The nodules found in the beds about the last-named point, though in my opinion originating beneath swampy deposits, have apparently been, in part at least, swept from their original beds by the rivers which enter the sea at that point, and have thus been concentrated in estuarine deposits.

Although local concentrations of phosphatic nodules other than those now known may well be sought for in the Southern States, I do not think that the precise conditions or character of the deposits as found at Charleston should be expected to repeat themselves elsewhere. It is characteristic of the process of concentration of phosphatic as well as of other matter into nodules, that the material takes on a great variety of aspects, each proper to a particular site, and this although the surrounding circumstances of the several localities may apparently be identical.

Next lower on the geologic section we have, in the tertiary region of the Mauvaisis Terres, extensive deposits of vertebrate remains which may possibly yield some commercially important supplies of bone phosphates. Although none of the existing sources of supply

of these materials come from deposits of the nature of those found in Nebraska, the conditions of that remarkable region are so peculiar that it will not be well to pass it by without inquiry.

While the American cretaceous deposits are, as a whole, decidedly different from those of the Old World, the greensand beds of the section in the two countries present considerable likeness in their characters. It is probable that in this country, as in Europe, considerable parts of the cretaceous section are somewhat phosphatic, and that these beds containing disseminated phosphatic matter have been in many places exposed to the process of leaching in former geologic periods: therefore we may reasonably search in the cretaceous beds of this country for the same class of phosphatic deposits which have proved so important in the northern parts of Europe.

Although some peculiar deposits of phosphate have been found in the Devonian rocks of Nassau, it may safely be assumed that below the line of the cretaceous we have no facts to guide us in our search for phosphates until we come to the horizon of the upper Silurian limestones, at about the level of the uppermost beds of the upper Silurian, as far as that level can be determined by the perplexing assemblage of fossils. There occurs in Bath County, Ky., a thick bed of much decayed, very phosphatic siderite. This deposit covers but a small area, and consists of a patch of limestone of about fifteen feet thick, which has been converted into siderite by the leaching of iron-bearing waters from the ferruginous Ohio (Devonian) shales which formerly overlaid the bed. Since the escarpment of the Ohio shales retreated beyond this bed, it has been subjected to oxidation, and is now in the main converted into a much-decayed limonite. Beneath this limonite there is a greenish argillaceous sand, which contains frequent nodules of lime phosphate. These nodules are smooth-surfaced, and not unlike some of the nodules from the Carolina district. They contain as much as 92 per cent of lime phosphate. It seems likely that these nodules were formed by the leaching-out of the lime phosphate from the overlying ferruginous layers, which has completely removed the lime carbonate, but has not removed the whole of the less soluble lime phosphate.

SECTION AT OLYMPIA, BATH COUNTY, KY. (PRESTON ORE BED).

Although this deposit of nodules is not of sufficient abundance to have any economic value, it is clear that we have in it an indication of a method where, by a slight variation of the conditions, important beds of nodular phosphates might be found.

In the horizons of the Cambro-Silurian section, or, as it is generally called, the lower Silurian, there is much greater reason to expect the occurrence of workable phosphates than in the beds immediately above. It is likely that the most important of the Spanish deposits belong in strata of this period, and the Welsh deposits of this general age are of noteworthy extent. We know, moreover, that the commoner marine animals of this part of the geologic section were particularly adapted for the secretion of lime phosphate.

The search of this portion of the section for phosphates should be directed to two ends: first, to finding beds of very phosphatic limestone; and, second, to discovering veins formed by a segregation of lime phosphates either in the form of the Spanish deposits referred to by Dr. Penrose or in the condition of nodular accumulations. The area of rocks of these lower Silurian and Cambrian periods in this country is very extensive, and so far there has been no search of them for phosphatic materials. The little work done in Kentucky during the above-mentioned geological survey served only to show that the proportion of lime phosphate in the rocks is extremely variable, and that in certain beds it is so considerable that the ma-

¹ See Quarterly Journal of the Geological Society, London, xlii., 1886, p. 325.

terial might advantageously be used in a local way for fertilizing purposes.¹

The search for phosphatic materials in the stratified rocks demands a method of inquiry that has not yet been applied to the study of our rocks. It seems to me that the method, or rather methods, should be as follows:—

First, there should be a careful inquiry to determine the share in which the several important groups of rock-making organic forms contribute phosphatic matter to strata. This can be accomplished by carefully comparing the chemical character of particular strata with the fossils the beds contain. When this determination is made, we shall have one means of guiding our inquiries, which will surely be of great value in the search for bedded phosphates.

Second, we should have a carefully executed chemical survey of our stratified rocks. Enough can be gathered from the scattered records of chemical analysis to make it plain that certain features of the chemical character of particular beds or divisions of strata often extend laterally for great distances. This is shown in a general way by the character of the soils formed of the waste of particular horizons; for instance, the deposits of the horizon on which lies the Cincinnati group of this country and the equivalent deposits of Europe are nearly always well suited to grasses and grains, and have a great endurance to tillage. It is now desirable to take these beds which promise to afford mineral manures, and subject each stratum to analyses which shall determine the quantity of phosphoric matter, soda, and potash which they contain, so that their fitness for use as mineral manures may be ascertained.

Below the level of the Silurian and Cambrian strata, and partly in those sections where they have been much metamorphosed, lies the field of the vein phosphates. It is more than likely that in this vast thickness of rocks, with their development in this country, there are many extensive sources of this class of phosphates which await discovery. As yet no careful search has been made for such veins in any part of the United States. The regions most likely to contain such deposits are found in the central parts of the Appalachian system of mountains, especially in the section from Virginia southward; in the Archæan district of Missouri and Arkansas, and in the vast region of highly metamorphic rocks of the Cordilleran district, extending from the Rocky Mountains to the Pacific Ocean. It is true that at present the economic value of phosphatic deposits in the western part of the continent would probably be small, on account of the great cost of transportation to the seaboard districts. But the growing use of phosphatic manures in the Mississippi valley, and the rapid exhaustion of the soils of that district, will soon give commercial importance to any sources of supply of phosphates that may be found in any parts of the Cordilleras which are convenient to transportation.

A proper study of the mineral manures of this country can best be carried on by means of a well-considered co-operation between geological explorers and the experiment stations of the several States. At present the methods of using mineral phosphates are extremely costly. Not only is the material brought into the soluble condition by saturation in sulphuric acid, but it is then mingled with ammoniacal and other matter to increase its effect as a fertilizer. The result is, that although a ton of Carolina phosphate now costs but six dollars, the average price of the manufactured product to the consumer at the phosphate factories is about thirty dollars per ton. It is probable that the essential value of the phosphatic ingredients to the plants of most soils is not enhanced by this costly treatment, though an incidental but dearly purchased gain, in the case of some crops, is obtained from the ammoniacal matter. The only effect of the superphosphatizing on the phosphatic matter is to make it more immediately absorbable by the plants. If placed on the soil without any other preparation than grinding,

lime phosphate will slowly pass into a condition in which it may be absorbed by plants, while, if treated with sulphuric acid, it is, for a time at least, in a soluble state. That this treatment is not essential is well shown by the fact that the phosphatic matter derived from the rocks is brought into a condition for absorption by the ordinary process of decay in soils. Our present costly method of applying phosphates has come about through the commercial history of artificial manures, which is as follows:—

Before guanos were brought into use, the English farmers had learned that they could profitably use the phosphatic marls of their tertiary and cretaceous deposits without any artificial preparation. If guanos had not existed, it seems likely that mineral phosphates would have always been used in this way. When the Peruvian guanos came into use, they afforded a much more stimulating material than any other purchasable manures, and in a short time they established the type of commercial fertilizers. When the sources of supply of these guanos became in part exhausted, artificial compounds, formed on a basis of rock phosphates or apatites, were devised to take their place. These were made to imitate the effect of the guanos as closely as possible. Like them, they gave a quick though temporary stimulus to the soil, enabling the farmer to obtain the greater part of the return for his investment in the season following the application of the high-priced manure. Very generally the fertilizer, guano or compounded material, was applied with the seed or dibbled in the soil alongside the young plant; so that it would be immediately available in the first stages of its growth, and, what is a more important consideration, that it might take less of the substance to give the effect than if it were sown broadcast over the surface or mingled with the soil of the whole field.

In this way a habit has been established in the art of using phosphates, as well as in the composition of the material, which, like all commercial habits, is hard to overcome. The question to be determined is as to the utility of phosphates with other modes of treatment than those which are applied in the imitation guanos. At present this treatment requires the commingling of the lime phosphate with a number of costly substances. The manufacture can only be advantageously carried on at points remote from the districts where the materials are produced, and remote from the fields where they are used, so that the costs of transportation are great. The problems to be solved by the agricultural stations are as follows:—

- (1) As to the effect, immediate as well as permanent, arising from the application of ground phosphatic rock commingled with other materials on soils used for the production of different crops.
- (2) As to the degree of comminution of the material which is most advantageous. It seems possible that fine pulverizing may take the place, in a measure, of superphosphatizing.
- (3) As to the effect of mingling the powdered rock with ordinary barnyard manure, peat, and other similar substances.
- (4) As to the effect of lime phosphate used alone on soils containing different mineral constituents; as, for instance, those having considerable proportions of lime carbonate, and those having but little of that substance.
- (5) As to the proportion of the lime phosphate which it is necessary to apply in order to produce different degrees of effect upon the fertility of soils.

It is desirable that these and other experiments should be tried at a number of stations in different parts of the country, in order that the needs of various crops may be considered, and the effect of the fertilizers on different classes of soils ascertained.

The effect of a small amount of lime phosphate on the fertility of the soil is clearly great; but, so far, we do not know with accuracy the amount necessary to produce a given effect. The range in phosphoric-acid contents in the soils of Kentucky, as determined from many hundred analyses, varies from 0.540 to 0.061.¹ In most cases the fitness of the soil for grain-tillage is measurably proportionate to the phosphatic contents. It seems almost certain, though not yet demonstrated, that the greater part of the phosphatic matter in the soil is in the state known as insoluble and that it only becomes in small part, year by year, soluble, or, in other words, fitted for assimilation by plants. Whenever the soil

¹ Among the analyses recently made by the chemists of the Kentucky geological survey is one which indicates the presence of phosphoric acid in considerable quantities in the limestones of Cretaceous age exposed at Stewart's mill, on Lulbegrund Creek, in Clark County. This partial analysis, for which I am indebted to Mr. John R. Proctor, the present director of the Kentucky survey, is as follows: viz.,—

Lime carbonate	21.380
Magnesia	3.055
Phosphoric acid	9.710
Potash	.830
Soda	.228
Silicious nodules insoluble in acids	27.580

¹ See report of Dr. Robert Peter in Reports of Geological Survey of Kentucky, new series, vol. v. 1876.

contains the quantity of lime which characterizes the better class of Kentucky soils, it is supposed, that, even if soluble phosphatic manures are applied, the superphosphate becomes again insoluble by taking up a molecule of lime. It is therefore an interesting question as to the means by which the lime phosphate enters the plants. It may be that the solution is effected through the action of the various humic acids of the soil, or it may arise from some specific change which takes place at the contact of the soil with the roots. It is evident that this point requires precise determination, for on it will depend further experiments as to the methods of applying phosphatic manures.

There is yet another point on which we need experiments. Many of our rock phosphates, especially those which are distinctly bedded, contain low percentages of phosphatic matter. Many of our lime phosphates contain crystals of apatite and calcite so intermingled that it is not possible to separate them; yet from these deposits it will be easy to produce a mixture of lime carbonate and lime phosphate containing from 10 to 20 per cent of phosphoric acid. The value of such material for manure has never been determined. If it can be used in a way which will give to the fields the full value for both the lime and the phosphorus, it will open a way for an extensive production of cheap fertilizers.

The foregoing considerations give the general results of the preliminary inquiry into phosphatic manures, of which Dr. Penrose's work forms a part. Before we go further into these studies, I much desire to have the criticism and advice of others who have considered this subject. It is with this view that I have ventured to give in the foregoing pages an account of the aim of the inquiries I have in hand. The questions are at once chemical and geological, and demand much co-operation for their solution. Much of the work of searching for the unknown phosphatic deposits of this country will necessarily have to be undertaken by local students of geology or by commercial explorers in search of such deposits. Unfortunately, the unfamiliar aspect of the various forms of phosphatic deposits will make this task under any circumstances difficult. There is no substance of equally wide diffusion among those of considerable commercial importance, which, in the present state of popular knowledge, so readily escapes detection as lime phosphate.

BOOK-REVIEWS.

Social Progress. By DANIEL GREENLEAF THOMPSON. London and New York, Longmans, Green, & Co. 8°. \$2.

THIS work is an inquiry into the foundations of social life and the means and methods of progress. The first part deals with the conditions of social progress; the second, with the means of promoting it. The work contains nothing that is specially new or striking, but is rather a restatement of the general principles of free government and social improvement as viewed from the standpoint of an evolutionist. The author's style is clear and flowing, so that the book is easy and agreeable to read; and there is much in it that thinkers of all schools will agree with. Mr. Thompson begins with a discussion of liberty and law, which he declares to be inseparable. All men, he maintains, must have equal rights and equal protection under the law; but as men and classes differ in power, the maintenance of equal rights has always been difficult. In former times the difficulty arose chiefly from military ambition and priestcraft, while in our time the danger that threatens us is that of a plutocracy. The main defect in this portion of Mr. Thompson's work is its inadequate recognition of the moral element in society. He does indeed recognize it, but he gives an altogether insufficient account of it. He bases society on self-interest alone, and reduces even benevolence itself to selfish prudence. He inquires why it is that we take pleasure in promoting the good of others, and answers the question thus: "Upon investigation we cannot fail to be led to the conclusion that the foundation for this is the selfish consideration of how delightful it would be if everybody else besides ourselves were animated by the desire and purpose of helping instead of hurting his neighbor" (pp. 63, 64); in other words, we do good to others in order that they may do good to us. The second part of Mr. Thompson's treatise treats of radicalism and conservatism, of the need of frequent change in order that society may progress,

and of the best way of effecting such changes. It offers many interesting remarks on the need of care in the formation of opinion, on the folly of attempting political changes before the public is ready for them, and on other matters incidental to the subject. On the whole, this part of the work, though dealing with less fundamental questions than the first part, is more satisfactory.

Scientific Religion. By LEIPART OLIPIHANT. Buffalo, Charles A. Wenborne. 8°. \$2.50.

WHY the doctrine taught in this book should be called scientific we do not know, for its characteristics are all of the opposite kind. Mr. Oliphant sees, as most other men do, that the old religious views will no longer suffice, and he undertakes in these pages to furnish a substitute. He believes in communication with departed spirits, who will teach us many important truths and render us invaluable aid if we will but listen to them. He holds that "the unseen world teems with intelligences, whose action upon this one is very direct, and is governed by laws." "This," he declares, "is a fact of my own personal experience." Spirit, he maintains, is only a higher form of matter, and the spirits in the unseen world communicate with us by the "interlocking of atoms." It is sad to learn, however, that the unseen spirits are not all good, and that the bad ones exert a baneful influence upon us, some of our worst impulses being due to their "infestation." Insanity, also, is due to them; and "when, therefore, we read in the Gospels of the cures by Christ of men possessed by devils, the expression is literally accurate." It depends on us, however, whether we will be influenced by the good spirits or the bad ones; and, in order to obtain the highest favors from the spirit world, we must become "bisexual." Adam, we learn, before the fall, was bisexual, and though his feminine part was separable from the masculine, the two were still one, this being possible in the case of Adam and Eve because their atomic structure was "four-dimensional." Christ, also, was bisexual, and, in fact, came into the world to restore the bisexual principle. Such is the stuff that Mr. Oliphant offers us as a new religion, and he expects men to abandon the Christianity of the churches for this! A large part of his book is devoted to a mystical interpretation of the Bible, and the rest is mainly occupied with the doctrine of spirits. We regard the appearance of this work and others of a similar character as one of the strangest signs of the times, and as indicative of a mental aberration that is truly amazing.

German Commercial Correspondence. By JOSEPH T. DANN. London and New York, Longmans, Green, & Co. 16°. 80 cents.

THIS book is of the *multum in parvo* kind, containing a great deal in a small compass. Its author was at one time assistant master in University College School in London, and it is intended not only for the use of schools and classes, but also for self-tuition. Specimens of letters are given for translation from German into English and from English into German. Copious notes, sufficient to enable the student to understand and render every idiom, are supplied, being placed at the end of the book, so that students may learn them by heart before translation is attempted. At the end of each section, subjects for writing letters similar to those contained therein are given, by way of exercises, so as to enable students to turn the study of the section itself to account. Copious vocabularies, German-English and English-German, are appended, embodying all the words which the student cannot be expected to have acquired in an elementary training. The idioms and peculiarities of the language have received special attention, so that the student may know not only what to do, but what to avoid.

French Commercial Correspondence. By ELPHEGE JANAU. London and New York, Longmans, Green, & Co. 16°. 80 cents.

THIS and its companion, the "German Commercial Correspondence," mentioned above, are constructed on such a plan that they may be used separately or together. The substance of the letters, in French or German, forming the first part of each section, is the same, and the English letters forming the second part are identical in the two volumes. In the third part are subjects for letters,

giving the student an opportunity to turn to account the study of the preceding two parts, and to acquire a greater command over the language and more self-confidence than by the process of mere translation. Like its fellow-volume in German, this contains a copious double vocabulary.

Elements of Plane Analytic Geometry. By JOHN D. RUNKLE. Boston, Ginn & Co. 8°. \$2.

THE author of this work is Walker professor of mathematics in the Massachusetts Institute of Technology at Boston, and the matter composing the first eight chapters of the book has been used by the students of that institute for some few years. The needs of the students have not been lost sight of in the preparation of the book. Though it is necessary that they should become reasonably familiar with the more elementary and fundamental parts of the subject, still the time which they can devote to it is limited. Therefore the earlier chapters are treated with somewhat more fulness than is usual in books of the kind, and particular care has been taken to illustrate and enforce all parts of the subject by a large number of numerical applications. Only the simpler problems have been selected; and an effort has been made to have the number of problems proportioned to the time which the students can profitably devote to them. The latter part of the book is based on a treatise upon conic sections by Charles Smith, M.A., of Cambridge, England, the later chapters following Mr. Smith's work quite closely. Teachers and students besides those in the Institute of Technology will find Professor Runkle's book adapted to their needs.

The Beginner's Reading Book. By EBEN H. DAVIS. Philadelphia, Lippincott. 12°. 42 cents.

THIS little book contains a series of elementary lessons for youngest readers, with appropriate pictorial illustrations, and in these respects it does not differ essentially from other works of a similar kind. But the author has a theory about the best method of teaching children to read, and he explains his method in an introduction. He begins his instructions by talking with his pupils about the various objects provided for them, thus leading them to frame brief sentences about the objects. These sentences are then placed upon a blackboard in script letters, and the children are taught to read them; and not until some twenty weeks have been spent in this way are the pupils to take up their reading-books and begin to read print. Whether this is the best way to teach children to read, experience must decide; but it seems a roundabout process. However, there is an old saying that the shortest way across is sometimes the longest way round; and so Mr. Davis's method may, after all, be the best.

AMONG THE PUBLISHERS.

WE reproduce in this number three illustrations, "The Kitchen," "Jim," and "Canadian Grouse," from "B. C. 1887," a book of travel and adventure in British Columbia, published by Longmans, Green, & Co., and reviewed lately in these columns.

— A contest has long been waged among educators as to which is of greater practical value in education, the classics or the sciences. For many years the friends of the classics had it pretty much their own way, but of late the scientists have been putting in some strong pleas in behalf of their side of the case. The latest of these, about to be issued in book form by S. C. Griggs & Co., Chicago, is by the well-known author and scientist, Dr. Alexander Winchell, University of Michigan, and is entitled, "Shall We Teach Geology?" Few, if any, American writers are better qualified for discussing this question than Dr. Winchell. While his treatise is a special plea for teaching geology in the public schools, it is intended to cover the whole ground of contest between the sciences and the classics, and hence promises to be of great interest, not only to teachers, but to all who are interested in observing the tendencies of modern education.

— Charles Scribner's Sons have just ready "French Traits," by W. C. Brownell, an analysis of French character and French society. The method of criticism is comparative throughout, the social

customs, intellectual habits, art instincts, and moral standards of the French being brought into juxtaposition with those that prevail in the United States. They have also just ready a treatise on metaphysics, by Dr. James McCosh, entitled "First and Fundamental Truths," which is regarded by the author as the copestone of what

From "B. C. 1887," Longmans, Green, & Co. THE KITCHEN WINDERMERE STORE.

he has been able to do in philosophy, and in which he formulates and explains the fundamental law governing the associated mental exercises. Finally, they have a new and revised edition for 1889 of Thomas A. Janvier's "Mexican Guide."

— A. C. Armstrong & Son have just published three important works on the Asiatic continent,— "Through the Heart of Asia over the Pamir to India," by Gabriel Bonvalot, which has been translated

From "B. C. 1887," Longmans, Green, & Co. JIM AND THE SORREL NAG.

from the French by C. B. Pitman, and is published in two volumes, with 250 illustrations by Albert Pepin; "The Industries of Japan," by Professor J. J. Rein of the University of Bonn, which gives an account of the agriculture, mining, forestry, arts, and commerce, from travels and researches in Japan, undertaken at the cost of the Prussian Government; and a second edition of the same author's work on "Japan, Travels and Researches," which, by verdict of the London *Spectator*, will be "the standard authority in such mat-

ters" for a long time to come. The new volume in the Book-Lovers' Library is "Foreign Visitors in England, and What They have thought of Us," which makes the ninth in this series.

— The new *Atlantic* index is rapidly approaching completion.

— Houghton, Mifflin, & Co. have just issued Henry S. Dana's "History of Woodstock, Vermont."

— Lee & Shepard have just published "Essays, Religious, Social, Political," by David Atwood Wasson. The book includes an autobiographic sketch, and a biography of Mr. Wasson, by his friend and contemporary, O. B. Frothingham.

— "Franklin's Works," published by subscription at five dollars a volume, are now quoted at ten dollars each, or one hundred dollars for the set. Remarking on this, the *Critic* says, "What a pity it is, by the way, that the Putnams issued so small an edition! To think that only 600 out of 60,000,000 of free-born antimonopoly Americans can own a copy of Franklin's complete works!" We trust some day Messrs. Putnam will see their way clear to publish an abridged edition.

— G. P. Putnam's Sons have in preparation a translation, by Miss Ruth Putnam and Mr. Alexander Arbuthnot, of the "Histoire de la

From "B.C. 1887."

Longmans, Green, & Co.

THE CANADIAN GROUSE (DENDRAGAPUS CANADENSIS).

Participation de la France à l'Établissement des États-Unis d'Amérique," by Henri Doniol. The edition will probably be a limited one. They have also in press a work by Theodore Roosevelt, on the early history of our Western territory, entitled "The Winning of the West and South-west, from the Alleghenies to the Mississippi." This is expected to be complete in two volumes, the first of which will cover the period 1769-83; that is, to the close of the Revolution.

— William Wood & Co. have recently inaugurated a new and original plan for furnishing the most recent, the most advanced, and the most authoritative writings of prominent instructors and practitioners of medical science throughout the world. They have issued the first of *Wood's Medical and Surgical Monographs*, containing three articles,—"The Pedigree of Disease," by Jonathan Hutchison; "Common Diseases of the Skin," by Robert M. Simon; and "Varieties and Treatment of Bronchitis," by Dr. Ferrand. They propose to issue one of these monographs per month, covering the details of experiments and methods which have led to the latest discoveries and newest practice. The translations from foreign languages will be intrusted to experts on the subject as well as good linguists. All that is being learned and done throughout the world will thus month by month be reported in the best manner. The first issue is one of 259 pages, and this will be the average size.

— Houghton, Mifflin, & Co. will soon publish "Home Gymnastics for the Well and the Sick," containing directions how to preserve and increase health, also how to overcome conditions of ill health by simple movements of the body, adapted to all ages and both sexes, edited by Dr. E. Angerstein, superintendent of the gymnasia of the city of Berlin, and G. Eckler, head teacher of the Royal Institution for Educating Teachers of Gymnastics, translated from the eighth German edition by Mr. Berthold Schlesinger, a well-known business-man of Boston, and amply furnished with illustrations.

— The supplement has become an important feature of *Harper's Weekly*. "American Men-of-War," by Lieut. J. D. Jerrold Kelley, U.S.N., with twenty-seven illustrations, forms the supplement to the issue of Feb. 9: that to the Feb. 16 number is devoted to an illustrated description of Omaha, Neb.

— All teachers of modern languages feel the need of varying the reading-matter used in their elementary classes. Not only do they themselves tire of going over familiar ground, but their pupils are apt to conceive a certain contempt for a language which they see represented year after year by the same two or three time-honored productions. D. C. Heath & Co. are issuing a series of texts, selected from the best writers, in inexpensive editions. To the twenty German and French texts of their list, they have just added, by purchase of C. H. Kilborn, "The Story of Ali Baba and the Forty Thieves;" "Der Zwerg Nase: Marchen von Wilhelm Hauff;" "Chamisso's Peter Schlemihl;" "Heine's Die Harzreise;" "Choix D'extraits de Daudet;" "Souvestre's Confessions d'un Ouvrier." They will add to the above this week "Jeanne D'Arc," edited by Barrère.

— Thomas L. James, postmaster-general in Garfield's cabinet, will contribute his first magazine article to the *March Scribner*, entitled "The Railway Mail Service." Thomas A. Janvier ("Ivory Black") will tell a bunch of Mexican folk-tales and superstitions collected by him during his many trips in that country. Gilberto Cano, "the best waiter at the Café Anglais," in the City of Mexico, told him many of these strange stories. The city of Treves, in Germany, founded 2004 years before Christ, and later for a century capital of the Roman Empire, will be described by Professor W. B. Scott of Princeton, who has recently made a careful study of its antiquities. Henry James will contribute the end paper, "An Animated Conversation" on international topics between Americans and Englishmen who meet in a London hotel. The paper is in dialogue form.

— In *The Home Journal* of Feb. 6 is given a selection of the poems of the late George Perry, who for many years was literary editor of that journal.

LETTERS TO THE EDITOR.

*Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith.

Twenty copies of the number containing his communication will be furnished free to any correspondent on request.

The editor will be glad to publish any queries consonant with the character of the journal.

O'Reilly's "Greenland."

MR. PILLING'S "Bibliography of the Eskimo Language" has received a bit of undeserved criticism, which I am very glad to be able to correct. An unsigned review in the *Athenæum* (Aug. 4, 1888), which is, on the whole, quite fair, and even complimentary, finds fault with Mr. Pilling for including in his bibliography O'Reilly's "Greenland," "though that work is now generally understood to have been a literary mystification." This interested me, as I had consulted the work in question, which purports to be an account of the writer's visit to Greenland in 1817, and had inserted the title in some bibliographical work of my own, not yet published.

The fact of its being a "literary mystification" did not appear to be "generally understood" in America, whatever might be the case in England. On the other hand, there appear to me to be strong internal evidence that the writer had made a visit to Greenland, and that the undoubted rubbish with which the book is filled was merely due to the ignorance and conceit of the author.

I accordingly put myself in communication with the editor of the *Athenæum*, and after a while received, in reply to my inquiries as to the history of the book, a memorandum from the reviewer, — who, however, declined to reveal his name, — as follows: —

"The person who wrote 'O'Reilly's' work on Greenland is not known. The author had probably made a voyage on board a whaler, but the greater part of the volume is simply imagination. In the *Quarterly Review* for 1818, p. 209, it is eviscerated, and the small portion which is 'not absolute nonsense' pronounced 'either fiction or downright falsehood.'"

This seemed conclusive, but I naturally turned for further corroboration to the passage in the *Quarterly Review* referred to.

Judge of my surprise when I found, on the preceding page (p. 208), the following passage, which the *Athenæum* reviewer, had evidently neglected to read when he declared that the person who wrote the book was not known:—

“Our first impression, on taking up the volume, was, that, as the subject of the Arctic regions had become one of the fashionable topics of the day . . . some hanger-on of Paternoster Row had contrived, with the help of Egede, Fabricius, and the interminable Cyclopædia of Dr. Rees, to hash up a fictitious voyage to Davis's Strait, in order to gratify the eager appetite of the public, and at the same time to 'put money in his purse.' Recollecting, however, that the log-book of the ship 'Thomas,' of Hull, in which this voyage is stated to have been made, was within our reach, we turned to it, and found that *Bernard O'Reilly, Esq., was not, as we suspected, a phantom conjured up for the occasion, but that there actually was a person of this name, in the capacity of surgeon, on board that ship*” [the Italics are mine].

The process of “evisceration” referred to by the *Athenæum* reviewer then begins with great ferocity—too great, it seems to me, even for such a ridiculous book as it is. This, however, only proves, what is easily seen from reading the book, that it is quite worthless from a scientific point of view, and evidently the work of what we should call a “crank” nowadays, not that it is not the work of the man whose name appears on the titlepage.

If the *Athenæum* reviewer has no further evidence to submit in regard to the authorship of the book, I do not see how we can doubt that the book is genuine, even though it is not authentic (which is quite another matter), and that it was perfectly proper to insert the title in a bibliography of such extended scope as Mr. Pilling's work. In fact, it would have been a mistake for Mr. Pilling to omit the book from his list, in spite of all its glaring absurdities.

JOHN MURDOCH.

Smithsonian Institution, Feb. 18.

The Soaring of Birds.

OWING to the remoteness of my present situation, I have but just seen the query of Mr. Kent. The point which he makes is a good one. I see also that I made a slight misstatement in my previous article. In the first place, as before remarked, we have the force *AB* due to the weight of the bird, and the force *AD* due to the

excess of velocity of the wind over the velocity of the bird. These two forces may be combined into the resultant *AC*. This resultant is resisted by the force *CA*, due to the resistance of the air acting on the wings of the bird as he wheels in circles about the point *A*. The force *CA* is therefore proportional to a function of the velocity with which the bird moves in describing these circles. The greater the velocity of the bird, the greater the force. Now, this velocity which he is capable of attaining with regard to the wind is dependent solely on the absolute velocity of the wind with regard to the earth, and can never be more than twice as great; i.e., when he is moving with the velocity of the wind and in the opposite direction.

Now let the velocity of the wind be *x*, and the excess of its velocity over the mean linear velocity of the bird (with respect to the earth) in the same direction as the wind be *a*, then the mean linear velocity of the bird with regard to the earth will be *x-a*. We will suppose that the velocity of the wind is such that *CA=AC*: the bird will therefore continue to revolve about the point *A*, which will consequently be its mean position. It must, of course, be remembered, that, while these forces are in equilibrium, the bird is slowly drifting over the earth's surface in the same direction as the wind. Its mean position would therefore describe a horizontal line with respect to the earth.

Now suppose the velocity of the wind (*x*) to increase, while its excess over that of the bird (*a*) remains the same: *AC* will therefore remain constant. But the velocity of the bird with regard to the earth (*x-a*), and also his absolute velocity with respect to the surrounding air, have increased, and therefore *CA* has increased also. Accordingly, the bird will be carried above and to the right of the point *A*. In the mean time the bird is drifting rapidly towards the left, in the direction of the wind: he will therefore describe a path lying in the same general direction as the line *AG*, *Q. E. D.*

W. H. PICKERING.

Los Angeles, Cal., Feb. 11.

A RECENT number of *Science* (xii. p. 267) gives an account of a paper by Mr. G. K. Gilbert, containing a theory of the soaring of birds, which traces this phenomenon to the advantage gained by the bird in gliding to and fro between contiguous horizontal layers of a horizontal wind, moving at different rates. The theory presented is said to have been anticipated by Lord Rayleigh (*Nature*, xxvii. p. 534); but it seems to me to rest upon what is, apparently at any rate, quite a different assumption from that which Lord Rayleigh made.

Mr. Gilbert imagines a bird gliding to windward in the lower of two contiguous layers, and traces the changes which his relative velocity will undergo if he first pass into the upper layer, then turn in it, then move to leeward, passing into the lower layer, and finally complete a cycle by turning to windward. He concludes, that, after the completion of the cycle, the bird's velocity will have increased by twice the velocity of the upper layer relative to the lower, frictional resistance being left out of account. This result he obtains by assuming, that, after turning, the bird's velocity, relative to the medium in which he turns, will be the same as before; in other words, that during the turn his velocity relative to the earth will change by an amount equal to twice the velocity, relative to the earth, of the medium in which the turn is made; the change being an increment in the turn to windward, and a decrement in the turn to leeward. Of course, in accounting for the phenomenon of soaring, some assumption must be made as to the bird's power of regulating the magnitude and direction of the force exerted upon him by the wind. But it should be a reasonable one, and, if not evidently so, should be justified. Mr. Gilbert's assumption does not seem evidently reasonable, and yet he does not even refer to its having been made.

In another recent number of *Science* (xiii. p. 31), Professor Pickering has shown that in a uniform horizontal wind the phenomenon of soaring is quite consistent with the law of the conservation of energy, provided frictional resistance is not too great, but he does not show how it may be accomplished. Lord Rayleigh, on the other hand, has stated that a uniform horizontal wind certainly cannot help us to explain this phenomenon. With so emphatic a statement from so high an authority, one is fearful of rushing in where angels fear to tread in attempting an explanation on this hypothesis. Nevertheless I venture to submit to your readers the following considerations, showing, I think, how soaring may occur in a horizontal wind which has no differential motion.

The force exerted by a horizontal wind on a bird may clearly be inclined upwards; for the wind, striking the lower surface of the wing, is deflected downwards, and must therefore have been acted upon by the wing with a downward force. The wind must therefore have exerted on the wing an upward force. What the exact direction and magnitude of this upward force will be, will depend upon the velocity of the wind relative to the bird, the wing area, and the ingenuity of the bird in adjusting its wings. With a strong wind and a wing area large relatively to the mass of the bird, it

may readily be large enough to have a vertical component equal to the bird's weight, in which case the resultant force on the bird may be horizontal.

Let us suppose, now, that a bird is at any instant moving horizontally, in the same direction as the wind, and with a small velocity relative to the earth. Since the resultant force on him may be horizontal, he may continue to move horizontally with increasing speed. As his speed increases, the velocity of the wind relative to him diminishes, and therefore also, probably, the upward force exerted on him by the wind. Although, therefore, the resultant force on the bird may have been initially horizontal, it will not remain so even for a short time. But it may remain for some time very nearly horizontal; for, as the magnitude of the relative velocity diminishes, its inclination to the normal to the plane of the wings will diminish also. During that time the bird will move slightly downwards, and his velocity will increase. When his velocity has become so great, and therefore the velocity of the wind relative to him so small, that the resultant force on him begins to have a direction differing markedly from the horizontal, let the bird wheel and steer upwards to windward. Let us suppose that in wheeling he maintains his velocity relative to the earth as well as his elevation. Then, starting upwards with a considerable velocity, he will clearly be able to rise through a certain height before his velocity has been reduced to its initial value. Let him then wheel again, and he will now be in a position to repeat the cycle with the same starting conditions as before. Whether soaring has been accomplished or not, will depend on whether or not the height gained when moving to windward is or is not greater than that lost in moving to leeward.

To determine this, consider first the downward part of the cycle. Let W_1 be the mean vertical component, and W_2 the mean horizontal component, of the force exerted by the wind on the bird's wings. Let R be the mean resistance to the relative motion of bird and air (due to friction, etc.), which in this case helps the bird. Let w be the weight of the bird, h the height through which he falls, and d the horizontal distance he traverses. Then the work done on the bird by the vertical and horizontal forces will be $(w - W_1)h$ and $(R + W_2)d$ respectively (we may treat R as a horizontal force, because the path is nearly horizontal). Let H be the energy expended immediately or ultimately in the production of heat. Then the kinetic energy gained by the bird on the downward motion will be —

$$(w - W_1)h + (R + W_2)d - H.$$

During the upward motion against the wind, the mean velocity of the wind relative to the bird will be much greater than during the downward motion with the wind; but while the direction of the relative velocity during the downward motion was upward, during the upward motion it is downward. It seems reasonable, therefore, to suppose that the upward force exerted by the wind may be made by the bird the same as before, and may have, therefore, the same components, W_1 and W_2 . Let R' be the mean resistance of the air due to friction, etc. R' , in this case, impedes the motion of the bird. Let w , as before, be the bird's weight; and let h' be the height through which he rises, and d' the distance traversed horizontally. Then the work done by the bird against the forces acting on him will be —

$$(w - W_1)h' + (R' + W_2)d'.$$

If the bird wheels when the energy expended on the upward motion is just equal to that gained on the downward motion, he will be ready to begin his second cycle under the same starting conditions as his first, and we shall have, for determining the height to which he has risen, the equation —

$$(w - W_1)h + (R + W_2)d - H = (w - W_1)h' + (R' + W_2)d',$$

from which it follows that the gain of elevation

$$h' - h = \frac{Rd - R'd' + W_2(d - d') - H}{w - W_1}.$$

Since during the upward motion against the wind the mean value of the velocity of the air relative to the bird is greater than in the

downward motion, R' will be greater than R . But the bird can so steer his course as to give his path a greater inclination to the horizon than his downward path had: hence d' may be made smaller than d ; and thus $Rd - R'd'$ may, by good steering, be made positive. Also, d' being less than d , $W_2(d - d')$ will be positive. If these two quantities together are greater than H , $h' - h$ will be positive; and if, finally, the increase of energy represented by the elevation $h' - h$ is greater than the inevitable waste during the turns, the bird will have increased his elevation during the cycle.

It seems to me possible, therefore, for a bird to soar in a uniform horizontal wind; because, by falling slowly in the motion to leeward, he allows the wind to do a large amount of work on him, and, by rising rapidly in moving to windward, he may regain his former level without having to do so much work against the wind. If it is possible, the bird's path must clearly be a spiral about a line rising in the direction of the wind, not about a vertical line; and this agrees exactly with observed fact. J. G. MACGREGOR.

Dalhousie College, Halifax, N.S., Feb. 5.

Some Habits of the Omahas.

IN the article entitled "Some Habits of the Omahas," on p. 60 of *Science* for Jan. 25, was a slip of the pen, which I wish to correct. Both Omahas and Ponkas, who speak the same dialect, call the wild honey "bee-dung." The term "bee-gum" was given me in 1872 by a Ponka, my interpreter, who stated that it was not the old name. My Omaha informant, Samuel Fremont, does not wish incorrect statements credited to him. J. OWEN DORSEY.

Takoma Park, D.C., Feb. 13.

Sawdust Explosion.

I ENCLOSE you a cutting from the *Ottawa Journal* in reference to what is called a "sawdust explosion," as it is a somewhat unique phenomenon. Last winter one occurred in the Ottawa River opposite this city, near the place referred to in this article, which broke up the thick ice over a large space. The river-channel is deep, but it is filled with a great accumulation of sawdust from the large mills just above. This sawdust generates immense quantities of marsh-gas, and once in a while something seems to start it up suddenly in large volumes. These striking the under side of the ice with great force, burst it up in the manner here described. This is why they are called "explosions." The gas is never ignited.

"Mr. J. de St. Denis Lemoine, sergeant-at-arms of the Senate, was blown up in a sawdust explosion on the Ottawa River, Saturday, Feb. 9, 1889, at midnight. He escaped with a wetting, and will not snowshoe to Gatineau Point again. It was a jolly party of gentlemen who left the city Saturday evening for a tramp on the ice-bound Ottawa. It included Messrs. Riddington, Lemoine, R. Fleming, J. Travers Lewis, J. W. Pugsley, Charles Elliott, Laurence Taylor, W. Middleton, Bogert, G. A. Henderson, and some others.

"The snowshoers headed direct to Gatineau Point, where an enjoyable time was spent. They started for home shortly before midnight. Mr. Riddington led the way, the snowshoers following in Indian file at a distance of about ten feet apart. The leader cautiously picked his way, because an ominous crackle here and there gave warning of proximity to cold waters running a few inches beneath.

"Matters went well for a time, until, some little distance below the Rideau Falls, suddenly the snowshoers were startled by a terrific explosion. An instant later they saw Mr. Lemoine hurled in the air, and as suddenly fall back into a mass of broken ice. It was only the work of a moment to grasp the sash of Mr. Lemoine and haul him on to the firm ice, not much the worse for his partial wetting. There would have been a funeral had the sergeant-at-arms been in the middle of the explosion.

"Mr. J. Travers Lewis had a narrow escape. Fortunately he stopped for a moment to fix his snowshoe-strings, and, had he continued in the footsteps of Mr. Lemoine, would also likely have experienced a sad fate.

"The snowshoers say that in their opinion the sawdust question has been solved." ROBERT BELL.

Insurance.

DELAY IS DANGEROUS.

We call attention to the new form of Accident (indem-
nity) Insurance policies, which are written by the Mer-
chant's Casualty Insurance Association, 21 Park Row,
New York City. John S. Purdy, Secretary. These policies
cover weekly allowances of from \$10 to \$25, according to
occupation, at a cost of only \$6 a year exclusive of the
cost to join, which is \$5 payable once only. The public,
as a rule, carry life insurance, and the ordinary accident
policies issued by companies, paying a sum in case of
death, is not so desirable as one of these indemnity policies
in case of accidents, which are so plentiful in this fast age
with its railroad horrors, fast driving, electric wires, and
other countless forms of danger to which the public is con-
stantly exposed. The fact of the Association having no
unpaid claims, and its having just passed an examination
by the Insurance Department of New York State, shows
that the management is liberal with its policy-holders
and conservative in its action. The Association also des-
ires to secure energetic Agents in every village and town,
to whom territory and favorable terms will be given.

TO EMPLOYERS.

Having purchased the fixtures, good will, &c., of
the NEW YORK EMPLOYMENT BUREAU, at No. 681
BROADWAY, in this city, we request the patron-
age of the public in the future. We desire to
fill a long-felt want for an employment bureau,
where only the best grade of male help is dealt in,
and it is our aim to send ONLY such help as is or-
dered in every instance, and our patrons can rely
on us to send strictly first-class help, the references
of whom we personally investigate before sending to
any one. We simply request a trial, and are con-
vinced that we will give satisfaction in every case.
We have on hand help in every branch, which we
can send upon receipt of telegram or letter, AND
FOR WHICH WE MAKE NO CHARGE TO AN EMPLOYER.

7% Guaranteed Farm Mortgages 7%

The Guaranty Investment Company makes loans upon fertile farms in the choicest portions of Kansas and Nebraska and has adopted the policy of sending a Committee of its Investors each year to examine its loans and methods of business.

The Committee this year consisted of PROF. A. H. BERLIN, Principal of the High School Montrose, Pa., and MAJ. THEODORE L. POOLE, Ex-U. S. Pension Agent, Syracuse, N. Y. Both of these gentlemen are persons of the highest character and have the confidence of the Communities in which they reside.

The Committee has recently returned and has made a very interesting Report upon the general development of Kansas and Nebraska as well as the business of the Company. The Company will be glad to send this Report to any address.

SCIENCE

FRIDAY, MARCH 1, 1889.

THE ELECTRIC MOTOR IN FACTORIES.

ON Feb. 6 a visit was made to the factory of the C. & C. Electric Motor Company by the New York Electrical Society, accompanied by some of the members of the American Institute of Electrical

fact that each machine individually is in operation only for a short time, even in the busiest times of work, the sum total of the power consumed at any one time is but a fraction of that required to drive all the machines simultaneously.

Fig. 2, for which we are indebted to the *Electrical World*, gives the ampères delivered by the dynamo during the whole run of the factory for one day, the diagram shown being one selected from a

FIG. 1.—NEW TYPE OF C. & C. MOTOR.

Engineers. The arrangements for power transmission were explained by Mr. Harvey L. Lufkin, of the company.

The engine in the engine-room is belted direct to a 50,000 watt Edison compound wound dynamo, which furnishes light to the building, as well as the current for driving the motors connected with the shafting. Instead of belting from floor to floor, wires run up, connecting directly with motors suspended from the ceilings.

number which did not differ materially in outline, so that an average run is there illustrated. As will be seen, the electrical horse-power delivered by the dynamo even with the heaviest load, due in great measure to the current furnished to the incandescent lamps, never exceeded 18 horse-power; and at times of the day when little light was in demand, such as between 10 and 3 o'clock, the load averaged no more than 12 horse-power.

FIG. 2.—DIAGRAM OF CURRENT-DELIVERY.

On the floor working the heavy machinery, such as lathes, planers, drill-presses, milling-machines, on which are some thirty machines, four motors, connected to separate lines of shafting, do the work. Two of these are only of 3.5 horse-power, and two of 1 horse-power each. The small amount of power required is remarkable.

To one looking at the shop in operation, it seems hardly credible that machines of such small power should be capable of doing the work which is actually accomplished; but when we consider the

The average load on the dynamo is about 40 ampères, or about 12 electrical horse-power, which covers both light and power. The friction load on the engine is 6.4 horse-power, giving us a total of about 20 to 22 horse-power on the engine. The power which would be required to operate the factory in the usual way, by belting through the floors, was estimated to be between 30 and 50 horse-power, without considering the power required for lights, amounting to an additional 15 horse-power.

Every operator in the factory who has charge of a machine, be it a milling-machine or drill-press, a lathe or planer, has a certain and absolute direct and instantaneous control over the automatic valve-gear on the engine in the basement, through the medium of the belt-shifter on his machine. Suppose he is using a milling-machine. The piece being milled has finished its travel, and the machine is stopped by shifting the belt on to a loose pulley. A horse-power of duty has been taken off of the electric motor driving that machine: the tension on the motor belt relaxes to exactly that extent; the counter electro motive force in the armature of the motor instantly increases; and the horse-power of current, which is no longer called for in the motor, the dynamo in the engine-room ceases to generate; and the automatic valve-gear on the engine immediately adjusts itself to a shorter cut-off.

Another great feature in this method of factory construction is the independence of each department. A break-down in one, or a stoppage from any cause, has no effect on the other departments. Each floor is connected directly to the engine-room.

The accompanying illustration (Fig. 1) shows the improved form of motor now manufactured by the company. The motor is wound for 110 volt constant potential circuits, and is started by simply turning on the switch fastened to the front of the yoke, and stopped by turning it back again. The mechanical construction of these motors is excellent, the machine being interchangeable in every part. Every hole in each part of the machine is so drilled, even in the large bed-plate, that it is impossible for the workman to get a hole a hundredth of an inch out of the way; so that, when the machines are assembled, it is only necessary to take each piece indiscriminately out of a pile of finished parts, and bolt them together.

CONVENTION OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

The ninth semi-annual convention of the National Electric Light Association was held at the Exposition building, Chicago, Feb. 19-21. The attendance was large, the electric light and power interests of all parts of the country being well represented. A large number of electrical exhibits, including all kinds of electric light and motor apparatus, from insulating tape to an electric street-car in operation, added much to the interest and importance of the occasion. The building was, as might naturally be expected, handsomely decorated, and brilliantly illuminated, when necessary, by numerous constellations of incandescent lamps, many of them being effectively grouped in ornamental designs.

On Tuesday, the 19th, the convention was called to order by the president of the association, S. A. Duncan, who introduced the city electrician, Professor Barrett, representing the mayor of the city, who was unavoidably absent. It may be mentioned here, incidentally, that a city electrician is an official undreamed of until recently, when electric light and power matters have assumed an importance approaching that of the water-supply or public works department.

After the usual courtesies of the city had been extended to the members of the association by Professor Barrett in the name of the mayor, President Duncan, after duly acknowledging the hospitalities tendered by the authorities, delivered the opening address, a brief abstract of which we give. Mr. Duncan said, in effect,—

“But few of the gentlemen of this country who are commercially connected with the manufacture and distribution of electric light and power are aware that five years ago this month a handful of men met in Chicago, and organized a movement which has grown into the organization which is in session at the present time. The industry of electric lighting at that time was carried on with all the enthusiasm which comes with a new undertaking, and with the mistakes which are sure to arise in the commercial introduction of any great industrial agency. The gentlemen engaged therein, strangers to one another, working independently, with no attempt at harmony, with but little knowledge of one another's methods of business, with no established custom or precedent to guide them, came together for the purpose of deriving those benefits which invariably result from the deliberate discussion of those questions which are common to the experience of all electric-light men. To

even enumerate the topics which have been discussed at the various conventions of this association would consume more time than your president feels at liberty to take. Fortunately, the association is in possession of a complete set of published proceedings, and these volumes testify to the steady and rapid growth of the industry, and the increased information on the part of the whole electrical fraternity on the general subject of electric light and power.

“In the early days of this association the chief question was the question of arc lighting. The incandescent light had scarcely come into commercial use. No sooner had the questions involved in arc lighting been solved than the complicated questions involved in the distribution of incandescent lighting absorbed the attention of the fraternity. Following closely upon the problems involved in incandescent lighting came the question of electrical distribution of power, first for stationary motor purposes, and afterward for the purpose of electrical locomotion. This question is, perhaps, the most important one before us. To say that electrical power is not a success would be to reflect upon the scores of electrical railways in successful operation in this country, and upon the thousands of electrical motors that are commercially serving the wants of man.

“We may here profitably consider some figures indicating the growth of the electric lighting and power industry, the increase in the number of central stations, arc and incandescent lamps, electric motors and electric railways, now in operation. At the meeting of this association one year ago, it was estimated that there were not less than 4,000 central-station and isolated plants in operation in the United States: the number of central-station and isolated plants at the present time is 5,747. This shows an increase during the year of 2,067 plants, or, in other words, of 45.8 per cent. A year ago there were 175,000 arc lamps in daily use in the United States: at present there are 219,924,—an increase of 62,625, or a total gain of arc lamps for the year of 34.3 per cent. A year ago there were 1,750,000 incandescent lamps in use in the United States: at the present time there are no less than 2,504,490, making a gain of 754,990 incandescent lamps,—49 per cent increase. The increase in capitalization in electric-light companies of the United States during the year has been \$69,397,734.

“It is interesting to note some comparative figures upon the electric-railway industry. Six months ago there were 34 electric railroads in operation in the United States: during the last six months there has been an increase of 19, making at the present time a total of 53. Six months ago there were 83 roads in process of construction: there are 39 less at the present time, making the number of roads now under construction, not finished, 44. Six months ago there were 39 electric roads incorporated in the United States upon which construction had not yet begun: at the present time there are 42. Six months ago there were 225 electric cars in operation: since that time, 155 have been put into commission, making, at the present time, 379 cars in operation. Six months ago there were 244 cars under contract, but not in operation: this number has increased by 185 during the last six months, making a total of 339 electric cars at present under contract, but not running. Six months ago there were 138 miles of single track in operation: during the past six months there has been an increase of 157.5 miles, making a total at the present time of 294.5 miles of single track in operation. Six months ago there were 189.5 miles of single track under contract, but not in operation: at the present time there are 273.75 miles of single track under contract, but not in operation. It would be fruitless to draw elaborate deductions from these figures: they tell for themselves the story of prosperity and rapid growth throughout every department of the electric light and power industry.

“We are gathered not only for the purpose of seeing an exhibit of the latest forms of electrical apparatus and supplies, but primarily for the purpose of listening to papers and discussions upon all important electrical questions. Some of the subjects deserve special mention. Petroleum for fuel first received attention from this body at its last meeting. At this meeting several papers will be presented upon the subject. The question of the materials of underground conduits in relation to the insulating materials of cables will also be treated. The question of static charge on un-

derground cables, and the attendant puncturing thereof, will also be the theme of a paper. Electric-light stations as fire risks will be treated by an expert in fire underwriting, who has given especial time and attention to that branch of the subject. Municipal lighting will be the subject of one or two papers, and no doubt of a profitable discussion. The committee on underground conduits and conductors has carried on a correspondence with the electric-lighting fraternity, and it seems proper that the information gathered should be presented in Chicago, where the undergrounding of electric-lighting wires has been more practically carried out than perhaps in any other city in the world. This question, which is at present one in which diverse opinions are held by men of equal professional standing, is one which this association cannot afford at the present time to ignore or overlook."

After some routine business, came the report of the committee on patent legislation, which shows that much progress has been made in the direction of securing the establishment of a court of patent appeals. This court is to consist of three justices, appointed by the President, with the advice and consent of the Senate, to have appellate jurisdiction in cases touching patents, copyrights, trademarks, and labels. - "The expediency and propriety of, if not the necessity for, the establishment of such a court as contemplated by this measure," to use the language of the committee's report, "will not be questioned if proper consideration be given to the objects that will be attained by the passage of this bill."

It is claimed that such a court would enable the public and patentees to determine the value and validity of patents without serious and vexatious delays; that it would relieve the Supreme Court of much of the burden imposed upon it by this class of litigation; that practice in the patent office would become thoroughly fixed and understood, and the issue of worthless patents would be greatly diminished, if not entirely suppressed; and that it would tend to simplify the patent laws by construction, and settle questions of doubt which are often used by litigants for the purpose of injustice and oppression. Under the present condition of the business of the courts, it requires ordinarily from two to three years to obtain a decision in the circuit courts of the United States, and, if appealed to the Supreme Court, from three to four years are required to obtain a decision. The same difficulty and delay attend the determination of all other questions involving the determination of property rights. While this is true, it should be borne in mind that this species or character of property differs from all other kinds of property. The duration of the owner's title is arbitrarily fixed by law. The period is short, for the most part seventeen years. The Constitution imposes upon Congress the duty of securing to authors and inventors, for a limited time, the exclusive right to their respective writings and inventions. This duty is very imperfectly discharged, when, by the omission of Congress to provide proper means to determine questions arising out of patents, the life of a patent may be frittered away by the delays of the law.

The committee on insulation of wires and installation of plants being called upon for a report, it was shown that the duties of that committee were of such a character that no one engaged in the electric-lighting business would care to attempt to fulfil them: consequently there was no report to make, and the committee was accordingly discharged; as was also the committee on electrical education, which reported that Columbia College of New York had so effectively taken up the work of the committee as to render its further services unnecessary.

At the opening of the session of Wednesday, after the usual preliminary business was disposed of, the report of the underground committee was read. It contained a large number of answers to a circular issued by the committee relative to the operation of underground wires. The report was discussed by Professor Barrett, who said the underground problem was solved successfully in Chicago. Mr. W. H. Johnstone discussed the paper at length, and gave the results of experience with his own conduit, which has been laid in Philadelphia and New York. Mr. T. Carpenter Smith said that overhead wires, when well constructed, were the safest method of distribution. Mr. De Camp spoke of the non-success of running arc-light wires under ground in Philadelphia, and was joined therein by Mr. Charles Cooper and others. Mr. B. E. Sunny said that technically his underground arc wires

were successful, but their cost was very high, the expense of maintenance amounting to one cent per lamp per hour during an experience of ninety days.

The discussion induced by this report was exceedingly interesting, and made prominent the fact that many difficult problems relating to the transmission under ground of high-tension electric currents yet remain to be solved.

On Thursday, the last day of the convention, a resolution was adopted to the effect that the report of the committee on underground wires be recommitted, and three new members were added to the committee. This committee, the result of whose labors during the next half-year will be awaited with great interest, now consists of Messrs. Lynch, Barney, Kerr, Davis, Crocker, Sperry, Barrett, and Sunny.

A resolution was unanimously adopted by the association to the effect that the members of that body would decline to allow any electric current under their control to be used for the purpose of inflicting the death-penalty upon condemned criminals.

In the afternoon session the committee on insurance exchange made a report, describing the work accomplished by the New England Electric Exchange in the licensing of persons installing and operating electric-light plants, and recommending the organization of similar exchanges in every State.

Niagara Falls was selected as the next meeting-place of the association, the date to be determined by the executive committee; and the following officers were elected for the ensuing year: president, E. R. Weeks of Kansas City; first vice-president, A. J. De Camp of Philadelphia; second vice-president, E. A. Maher of Albany, N.Y.; executive committee, B. Rhodes of Niagara Falls, B. E. Sunny of Chicago, C. R. Huntley of Buffalo, Dr. O. A. Moses of New York, E. T. Lynch, jun., of Brooklyn, P. H. Alexander of New York, J. F. Morrison of Baltimore, and T. Carpenter Smith of Philadelphia.

Among the papers read at the convention were one by Mr. S. E. Barton, on "Electric Light Stations as Fire Risks," which was discussed by Messrs. Morrison, Alexander, and others; one by Mr. C. H. Rudd, entitled "Disruptive Discharges in Lead Cables," discussed by Messrs. Barrett, Lockwood, and Acheson; one by Mr. S. S. Leonard, on "Petroleum Fuel;" one by M. J. Francisco, on "Liquid Fuel;" and one treating of the "Advantages of Oil for Fuel," by Col. C. M. Ransom. The discussion of these latter papers was participated in by Messrs. Leonard, Lockwood, Ransom, and Francisco. Papers were also read by Mr. F. H. Whipple, on "Municipal Lighting," and by Mr. A. R. Foote, on "Public Ownership of Commercial Monopolies."

The interesting report of the committee on underground conduits and conductors excited a somewhat lively discussion, which was ably carried on by many of the members present. The further report of this committee at the next convention will be awaited with much interest, as the subject of putting electric-light wires under ground in our large cities has assumed great importance.

A party of sixty gentlemen, mostly electricians, visited the convention by special train from this city. The train consisted of three Pullman vestibule cars, a dining-car, and a combination car with bath-room and barber-shop. It was lighted throughout by electricity furnished by an Eickemeyer dynamo driven by a Brotherhood engine.

On the afternoon of Wednesday, after adjournment, a party of delegates and visitors to the convention paid a visit, by invitation, to inspect an installation of accumulators recently placed in the residence of Potter Palmer by the Electric Accumulator Company. The current is generated by one of the United States Company's dynamos driven by an Otto gas-engine. The plant works admirably, giving great satisfaction to Mr. Palmer as well as to the company which supplied it.

HARWOOD'S NITROUS-OXIDE BLOW-PIPE.

A SIMPLE and convenient form of compound blow-pipe, invented by Dr. G. F. Harwood of Worcester, Mass., is shown in the accompanying engraving. It is intended for use in scientific laboratories, technical schools, dental offices, and other places where a powerful and concentrated flame under perfect control is required.

The apparatus is so designed and constructed that it will take the necessary supply of nitrous oxide from the ordinary gasometer at low pressure, or from a gas cylinder at high pressure, and economically combine it with ordinary illuminating-gas in any desired proportion for producing and maintaining a flame of the requisite intensity.

In construction, the apparatus is simple and easily understood. It consists of an expansion-chamber or reservoir, *D*, provided with a lever stop-cock *A*, which is to be connected with the nitrous-oxide supply at the gasometer or cylinder by strong rubber tubing,

HARWOOD'S NITROUS-OXIDE BLOW-PIPE.

Above this reservoir is the mixing-chamber, *E*, with a lever stop-cock, *B*, to be connected by rubber tubing with the illuminating-gas supply. The expansion-chamber or reservoir is separated from the mixing-chamber by a diaphragm, which is provided with a regulating-valve, the stem of which projects upward through the mixing-chamber. By means of the small hand-wheel, *C*, on this stem, the admixture of the two gases may be perfectly controlled. The combined gases are conducted through the outlet *F*, and flexible tubing *J*, to the blow-pipe tube *G*. This tube is provided with interchangeable nozzles, by means of which either a large or a small flame may be secured. When not in use, the nozzle is supported by the curved wire standard *H*. The flange *I* is drilled for screws, by which the apparatus may be secured in any convenient position to the wall or to a shelf or bench.

BELLITE.

ON Tuesday, Feb. 5, a series of experiments were made at Chadwell Heath, England, with the new explosive, bellite, invented by Mr. Carl Lamb. A description of these experiments is given in *Engineering* of Feb. 8, 1889. Reference is also made to this explosive in the same journal for July 1, 1887, and in that for Nov. 9, 1888. The new series of experiments were fully as successful as those described in these articles, and the absolute safety of the new explosive has now been placed beyond cavil. The experiments were arranged in groups, each of which was intended to illustrate either a distinguishing characteristic of bellite or its adaptability to some specified end. The first experiment was intended to exemplify its use in submarine mining: 1½ pounds of the material was enclosed in a tin canister, and, on being fired by a detonator, the explosion sent the spray fully 150 feet high. The next group of experiments were made with the object of showing the perfect safety of the material, and that it could only be fired by a detonator. A bellite cartridge was broken in two, and one half thrown on a fire, where it slowly burnt away with a reddish flame: the other half, weighing about 2 ounces, was then exploded on a wrought-iron plate 12 inches by 12 inches by ¾ of an inch thick, the charge being tamped with clay. The shock bulged the plate to a

depth of about 2 inches, but did not pierce it. An even more convincing proof of its safety was afforded by the chairman of the company, who, holding part of a naked bellite cartridge in one hand, calmly applied a lighted fusee to the fragment with the other. The bellite charred and smouldered, but went out immediately on removing the match. The next experiment was a repetition, on a somewhat smaller scale, of one of the Middlesbrough experiments, described in the second of the articles quoted above. An iron weight, weighing 120 pounds, was dropped from a height of 18 feet on to a number of naked bellite cartridges supported on an iron plate. The test was repeated twice, as on the first occasion the weight fell somewhat to one side; but on the second trial, with more careful centring, the mass of bellite was crushed to a powder. This test was much less severe than the Middlesbrough one, when the weight was half a ton, and fell from a height of 20 feet; but a heavy weight of this character is not easily moved from place to place, and hence the reason for the lighter one. A small canister capable of holding 5 ounces was then filled with the fragments resulting from the last experiment, and laid on the web of an old Great Eastern Railway Company's steel-faced rail, the charge being slightly tamped with clay. On firing, the rail was snapped in two, a piece about 1 foot long being flung 6 yards, and smaller fragments much farther, while a pit 15 inches deep was sunk in the ground immediately underneath the position of the charge.

The next experiment was a repetition of one first made at one of the collieries of South Wales. In it 1 pound of ordinary blasting-powder and 1 pound of naked bellite cartridges were placed together in an open pit 1 foot 10 inches deep, and the powder ignited. Some pieces of the bellite were thrown out of the hole, and all were slightly charred, but none of it exploded.

To further illustrate the safety of the material, a fragment of bellite was fired from a large-caliber gun (No. 8) with two drams of powder, against an iron plate, without any explosion of the bellite occurring either in the bore of the gun or on striking the target. This experiment would, moreover, seem to prove that bellite is well adapted for use in shells, and the English Government is accordingly to be congratulated on not having spent large sums in acquiring the secret of melinite. It had been the intention of the experimenters to fire a bullet from the same gun at a target formed of bellite cartridges backed by an iron plate; but, owing to the jamming of a cartridge in the gun, this experiment had to be abandoned.

To compare the effects of bellite with those of dynamite, 2 ounces of each explosive were fired on wrought-iron plates measuring 12 inches by 12 inches by ¾ of an inch thick; each plate, with the object of rendering the conditions as uniform as possible, being supported above the ground by a narrow cast-iron ring about ⅝ of an inch thick, 3 inches high, and 11 inches internal diameter, the charge in each case being tamped with clay. Both plates were pierced through, but the rents in the one on which the dynamite had been fired were considerably larger, while, on the other hand, the bulge in this plate was only 2½ inches deep, as compared with 3 inches in the case of the other, thus showing the action of the dynamite to be more local.

The next series of experiments were made with a view to showing the adaptability of bellite to military purposes. To this end the ballistic properties of bellite and Curtis and Harvey's rifle-powder were first compared; a 6-inch ball, weighing 32 pounds, being fired from a mortar, first with ½ ounce of powder, and, second, with ¼ ounce of bellite, the weightings being carefully made in the presence of two representatives of the press. With the powder, the ball was thrown a distance of 40 yards 1 foot; and with the bellite, to a distance of upwards of 100 yards, the penetration into the ground being also much greater in this case.

Two mines had been prepared, one with 6 pounds of powder laid at a depth of 5 feet, and the other with 6 pounds of bellite laid at the same depth. In trying to explode these, however, it was found that in the passage of some of the spectators over the mine both fuzes had been pulled out from the bellite charge, and the attempt to fire it accordingly failed. A good idea of what the effects would have been, was, however, gained in the next experiment, in which a mine containing 8 pounds of bellite was fired underneath a length of railway laid down for the purpose. The explosion smashed both

rails clean through, and several of the sleepers were splintered, a large piece of one being flung fully 40 yards, while the crater formed was upwards of 12 feet in diameter. This, the most striking of the experiments, was also the last.

SCIENTIFIC NEWS IN WASHINGTON.

Bibliography of the Iroquoian Languages. — The Los Angeles Base-Line. — Deep-Sea Models.

Bibliography of the Iroquoian Languages.

SOME ten years ago Mr. Pilling of the Bureau of Ethnology entered upon the formidable task of preparing a systematic and exhaustive exhibit of all printed and manuscript works giving information respecting the speech of the native races of North America. The need of such exhibit had become strikingly apparent. For nearly four hundred years information had been accumulating respecting the North American aborigines, and this accumulated information had been printed in many lands in many tongues. The subject was fast becoming, or had already become, buried in the *débris* of its own literature. Special students found themselves consuming an inordinate amount of time in acquiring even an imperfect knowledge of the literature of the special subject of their study.

Recognizing this condition, the labor of preparing a bibliography of North American linguistics was, as already indicated, systematically entered upon more than ten years ago, and has been continued with only such interruptions as were necessitated by other official duties. The work before us¹ closes the third chapter in this work.

The first chapter or division of the work was a bibliography of the Eskimo languages, issued in 1887; the second, a bibliography of the Siouan languages, issued in 1888; and the third, that of the Iroquoian, now before us; to be shortly followed by the Muskogean, and later by the Algonquian and the Athabascan.

The aim to make the catalogue as exhaustive and complete as possible, and the dictionary plan of arrangement, carried to its extreme limit, remain the same as in the earlier bibliographies; and it may be added, that zeal in the pursuit of all information relating to the books catalogued, and fidelity in exhibiting this information, increase rather than diminish as time passes.

As a sample of Mr. Pilling's painstaking bibliographic research, the "Voyages of Baron Lathontan" may be cited. Seven pages of the bibliography are given to the careful and minute description of the eighteen editions of the work, which appeared in French, English, German, and Dutch. To collate these different editions, copies were borrowed from numerous sources, and photographs of titlepages made, that proof might be read from facsimiles. The careful scrutiny exercised in preparing these minute descriptions has developed the fact, that, from the original edition of 1703, two spurious editions of the same date were prepared. So far as ascertained, but one copy of the authentic edition is extant.

The catalogue contains, in round numbers 950 titles, of which 800 relate to printed and 150 to manuscript matter. Of these, Mr. Pilling has himself seen and described 850, or 89 per cent; and of the remaining 11 per cent, about two-thirds have been seen and described for this catalogue by his correspondents. Thus about 95 or 96 per cent of the entries are at first-hand; and, further, 61 per cent of the entries were compared directly with the original sources while the proof was passing through his hands.

Of the various languages included under the general term "Iroquoian," — viz., Cayuga, Cherokee, Hochelaga, Huron, Iroquois, Maqua, Minqua, Mohawk, Oneida, Onondaga, Seneca, Tuscarora, and Wyandot, — more than half of the material catalogued relates to the Cherokee and Mohawk only; most of the Bible, for instance, having been printed in each of these languages. Printed dictionaries of the Huron, Mohawk, and Onondaga, and manuscript dictionaries of the Seneca and Tuscarora, are in existence. There are in print rather extensive grammatical treatises on the Cherokee, Huron, and Mohawk, and fragmentary grammatical notes on several of the remaining languages. Of the Cherokee texts, all except two spelling-books, published in 1819 and 1824 respectively,

are in the Cherokee syllabary, these two having been printed before the invention of those characters.

The earliest printed record of any North American language appears to have been made by Cartier, whose first voyage was made in 1534, and the second in 1535. There is reason for believing that the original account of the first voyage contained a vocabulary of the people of New France; but, so far as known, no copy of this book is in existence, and the date of its publication is not known. The account of the second voyage was published at Paris in 1545, and contains a Huron vocabulary.

This is one of the rarest books in the entire list, only two copies having been known for the last three hundred years. Of these, one was bought in 1851, and lost in a ship on its way to America. The other and only known copy is in the British Museum. Of this "unique," Mr. Pilling gives a facsimile of the titlepage. Facsimiles are also given of several other rare, curious, or specially interesting books.

The work contains eight pages of addenda, which accumulated while the copy was in the printer's hands.

A chronologic list of authors at the end of the volume, covering eighteen pages, begins with Cartier in 1545, and ends with a list of nearly forty works issued in 1888. From an inspection of this list, it appears that interest in matters relating to the Iroquois was never greater than at present; and, while the literature of the subject has been accumulating during the past three hundred and forty years, more than half of it has appeared within the last forty.

The Los Angeles Base-Line.

The "Yolo Base," as it is familiarly known to geodesists, being the base-line measured in Yolo County, Cal., in 1881, for the transcontinental triangulation of the United States Coast and Geodetic Survey, was, in point of rapidity and accuracy of measurement, the best work of the kind ever performed. That measurement was made under the immediate supervision of Professor George Davidson, assistant United States Coast and Geodetic Survey, with the five-metre compensating base apparatus, which had been constructed at the office of the survey in Washington, under the supervision of Assistant C. A. Schott, and in accordance with a design prepared and submitted by him. The length of the "Yolo Base" was 17,486.5119 metres (10.86 miles). It was measured twice throughout its entire length, with a third measurement covering less than half (42.8 per cent) of its length. The two measurements and partial measurement occupied a total of forty-six days.

The recent measurement of a Coast and Geodetic Survey base-line near Los Angeles, Cal., which was concluded on the 16th of February, afforded to Professor Davidson, under whose supervision the work was also done, an opportunity of fulfilling his announced purpose of "breaking all records" of base measurements.

The "Los Angeles Base" is roughly 17,496 metres in length, or 9.5 metres longer than "Yolo Base." Although the weather was extremely unfavorable, the work having been pushed in the frequent severe rain-storms, which converted the line into a route of deep mud, standing pools, and rushing streams, three full measurements were completed in 46.75 days, the average measurement per day having been 1,122.73 metres, against an average of 912.5 in the "Yolo Base;" the longest measurement in a single day having been 2,000 metres, against 1,620 metres on the "Yolo Base;" and the cost, exclusive of the expenses connected with the establishment of monuments at the ends of the lines, was \$8,000, against \$15,578 for the measurement of Yolo.

It is hardly to be expected that the accuracy of the Yolo measurement, which involved a probable error of ± 0.035 of an inch per statute mile, or .38 of an inch in a length of 10.8657 miles, will be surpassed by that of the Los Angeles Base. If it is even equalled, the Los Angeles Base measurement will signalize again the unequalled proficiency of American officers.

Deep-Sea Models.

Mr. E. E. Court of the Hydrographic Office of the Navy Department has published two excellent models, — one of the Atlantic Ocean, the other of the Caribbean Sea. These accurate and neatly finished models convey an excellent idea of the configuration of the bottom of the sea which is only inadequately expressed to the in-

¹ Bibliography of the Iroquoian Languages, by James Constantine Pilling.

experienced eye by means of contour-lines. Therefore these models have a highly educational value, and will be used to the greatest advantage in the teaching of geography. One of the features most strikingly shown in the model of the Atlantic Ocean is the extent of the continental shelves both of the Old and of the New World. The abruptness with which oceanic islands rise from the greatest depths is also well shown. The deep valleys of the Gulf of St. Lawrence, of the Florida Strait, south of Cuba, and at the mouth of the Kongo, appear very distinctly and clearly, and the bold relief of the Mediterranean Sea is seen to be in striking contrast to the oceanic depths. The undulations of the ocean are shown not less clearly. The great transatlantic cables are shown. Mr. Court deserves the thanks of teachers of geography for having undertaken a work of this magnitude. As the prices are very reasonable,—being ninety dollars for the model of the Atlantic Ocean, and seventy dollars for that of the Caribbean Sea,—it is to be hoped that universities and colleges will possess themselves of these valuable works. The author has also published photographs of these models, which show the relief to good advantage, although of course not as clearly as the models themselves.

HEALTH MATTERS.

London, Ancient and Modern, from a Sanitary Point of View.

In *Nature* of Feb. 7 is an abstract of a lecture delivered by Dr. G. V. Poore at the Sanitary Institute on Thursday, Jan. 24. Dr. Poore began by reminding his hearers that the mere age of London was one of the reasons why it became unwholesome. Roman London was buried deeply among rubbish of all kinds, much of which was putrescible, and therefore a source of danger in the soil.

Ancient London was well placed, and magnificently supplied with water, for, in addition to the Thames, there were many streams, such as Westbourne, Tybourne, the Fleet River, Walbrook, and Langbourne, which originally were sources of pure water. All these brooks, however, had become disgracefully fouled, and for very shame had been covered over. One great drawback to the site of London was the proximity of marshy land on every side except the north-west, and formerly from this cause malarial fever and dysentery were great causes of the high death-rate.

In mediæval London, and even down to the eighteenth century, the houses were not so closely packed as they are now. Reference to Aggas's map (time of Elizabeth) would show that there was a great deal of garden-ground within the city; and, on comparing this map with Newcourt's map (Charles II.), it was evident that just before the Plague and the Fire the crowding of houses had become very much greater than it was in the time of the Tudor monarchs, who discouraged building near or in London.

Parker's map (1720) would also show that after the Fire the houses were not so closely packed as in the days of the Stuarts, for in this map a surprising amount of garden-ground is visible within the walls. At this time, also, Moorfields was not built upon, and remained as a playground and air space, as it had done for centuries previously. That mediæval London was very unhealthy, a perfect fever-den, there could be no doubt. The Black Death in 1349, and the Sweating Sickness two centuries later, were times of great mortality which struck the popular mind; but it was not till 1593, when bills of mortality were first introduced, that we began to have any certain knowledge of the amount or the kind of disease prevalent. There was reason to think, however, that in the eighteenth century (after the Fire and the Great Plague) the deaths exceeded the births by about 600,000 in the hundred years.

The fatal diseases were mainly malarial fever, small-pox, typhus, measles, and (latterly) whooping-cough. The causes of the enormous mortality of mediæval London were due (1) to the marshy undrained soil, fouled with refuse of every kind; (2) the filthy state of the unpaved city, and a perfectly swinish condition of the houses of the lower orders; (3) the ill-nourished and drunken condition of the masses, among whom a taint of scurvy was very common; (4) the condition of superstition and brutality (as evidenced by the punishments and the pastimes), which made any measures of public health impracticable; (5) the bad management of epidemics, with a total neglect to separate the sick from the sound; and, finally, the

medical faculty were scarcely less ignorant and superstitious than their patients.

Turning to modern London, the lecturer said there had been a great and manifest improvement; but, when we looked at the low figure which is called the London death-rate, several things must be taken into consideration: e.g. (1) the London of the registrar-general included large districts, such as Lewisham, Wandsworth, Fulham, etc., which, in great part, were scarcely urban in character, and these, being occupied largely by well-to-do persons, lowered the average death-rate for the whole city; (2) London being a city in which wealthy people abounded, its death-rate must not, in fairness, be compared to a city packed with undiluted operatives; (3) the mobility of the population was so great, that this fact must vitiate the statistics, and it was to be remembered that nothing quickened the departure of an individual from London more than ill health; (4) the age distribution in London was very abnormal, it was largely recruited by selected adults from the country, and there was a great deficit in the extreme ages, among which (the very young and very old) death-rate is always highest; (5) again, the diminishing birth-rate (that for 1887 was 2.8 below the average of the previous ten years) very greatly diminished the death-rate in a city where 158 children out of every 1000 born die before they are one year old.

It was difficult to believe that Londoners were very robust, when more than 25 per cent of them had recourse to the public hospitals in the course of the year.

The cause of the diminished death-rate (which was very considerably reduced after every allowance had been made) was due (1) to the increase of knowledge, not only among doctors, but among the people generally, for it must be remembered that "self-preservation is the first law of nature;" (2) vaccination, and the modern plan of treating infectious diseases by the prompt separation of the patients, had done a great deal (the total absence of small-pox and typhus were mainly due to these causes); (3) the cheapness of food, clothing, and fuel, had, of course, diminished the tendency to disease, and the ease with which fresh fruit and vegetables were to be got had abolished the taint of scurvy which was so fatal to previous generations; (4) the water-supply had been improved, and the intake of the water companies was now removed to a portion of the river less tainted with sewage than that formerly in use; (5) although the system of sewage-disposal was an undoubted evil, and had caused three or four epidemics of cholera, and was the foster-mother of typhoid, still it was probable that so far the balance for good was in its favor, because it had removed a good deal of filth from dwellings.

The outlook in the future was dashed by three considerations: (1) The system of sewerage and water-supply had increased overcrowding by enabling houses of any height to be built without inconvenience to the occupant, and without any curtilage whatever; and, since all sanitarians recognized that overcrowding was the greatest of all sanitary evils, it was impossible to shut one's eyes to this danger. (2) There was an expensive and menacing "loose end" to sanitation in the shape of 150,000,000 gallons of sewage pouring into the Thames every day. The only proper destination of organic refuse was the soil, and it was not possible to see the end of the gigantic blunder that had been committed in throwing it into the water. (3) The rapid increase of population along the valley of the Thames, where sewage-disposal is on the same lines as in London, must make the English apprehensive for their water-supply, because the various tricks played with sewage in the shape of precipitations, etc., were not probably of a kind to make the effluent a desirable or a wholesome beverage. If the evil effects of free trade are to be counteracted, it will be by returning the refuse of towns free of cost to the impoverished agriculturist. "If we go on as we are going," said the lecturer, in conclusion, "and if our brethren in the colonies follow our bad example, as they appear to be doing, it will be a Chinaman rather than a visitor from New Zealand who will sit in contemplation on the ruins of London Bridge."

LARGE deposits of lead and silver ores and coal have recently been discovered in the district of Kouban, Russia, on the Black Sea.

ETHNOLOGY.

The Races of Egypt.

In the spring of 1888, Professor R. Virchow visited Egypt in order to inquire into the physical character of the Egyptians, his special object being to study the influence of the climatic and other conditions of the country upon man, and the other question, to compare the type represented on ancient monuments with that of the present inhabitants. Far-reaching conclusions have been made from studies of ancient paintings and carvings, but so far no sufficient anthropological basis existed for these studies. From this point of view, Virchow's work is of special interest to the ethnologist. The "Proceedings of the Royal Geographical Society" contain a full report of Professor Virchow's observations, from which we glean the following notes. The author says, that, although a final and satisfactory solution of the question is not yet to be expected, the solution of it in the case of Egypt is of great importance, because in that country the oldest historical data have made us familiar with men of the most highly developed civilization, who, through the position of their habitation,—an island in the sea of desert,—appear, in the most remote times, to have been shielded from foreign influences. At the time of the most ancient historical king of upper Egypt, King Menes, who reigned about the year 6000, we find a people with all the arts of civilization, an elaborate state system, a complete hierarchy, famous monuments of architecture and sculpture, and the rudiments of painting. But what was the state of things before the time of Menes? Here the threads of history break off short: the prehistoric period is filled up by later Egyptian and Grecian writers by means of a promiscuous collection of legends and myths, of which the student can take no account; although Professor Lant of Munich has endeavored, and not without success, to extract a reliable historical kernel out of the myths. Since 1869, positive data have been continually collected, and the result is to show that there has been an Egyptian stone age. But between the latter and the age of Menes, which presents the arts of civilization in complete form, there exists a yawning gap; and we seek in vain for a connecting link between any one of the oldest temples near the Sphinx, which itself presents no inscriptions and decorations of the later age, and the period of the stone age. As to the conventionalism of Egyptian works of art, we know now some details.

The supposition which was long held, that the ancient Egyptians at the time of Menes correspond with the type of man to-day existing there has been shown to be erroneous. Since the mummies of the old Egyptian kings, such as Sesostris, Settri, Rameses, and others, were discovered in 1870, and the crania of these conquerors have furnished us with measurable data, it can be asserted with safety that the existing images and statues of these rulers are not portraits, but that the latter were fashioned according to a certain conventional design. We are not, however, in the same position with regard to the sculptures of the older dynasties. Of these we only find scanty remains. Some crania, authenticated, but partially covered by inscriptions, are the only relics which we possess of that earlier time; viz., from the fifth dynasty backwards. With these, however, the statues agree. They are the skulls of short heads, while the fellahen of to-day have long heads. This, then, at least, may be taken as settled,—that a change of type in the case of the dynasties has taken place. The case is otherwise with regard to the ethnological figures on the Egyptian works of art which are represented beside the king. These show that in the oldest historical times the different types of people, which we find up to this day in Egypt and the neighboring countries, were just as sharply distinguished from each other as they are now. The question in this case, however, is not about portraits, but about types, in which the essentials (such as the kind of hair, form of head, etc.) remain the same, while the externals (the armor, clothing, etc.) change according to the periods. The oldest representation of a negro is found in the tomb of Una, one of the kings of the sixth dynasty. In the opinion of many, especially of Lepsius, the territory situated between the first and second cataracts, between Assuan and Wadi Halfa, which is the true Nubia or Ethiopia, is the district where the change of the Central Africans into the Egyptians took place. It is the same region which for four

thousand years, down to the present time, has been the object of strife between the northern and southern races. In the oldest times the country which lies immediately south of Assuan was called Kash (the biblical Kush). Lepsius tried to prove, from considerations of language, that the inhabitants of Kash were negroes. The investigations of Professor Virchow on the spot, however, have resulted in establishing the contrary. The Nubians have, in skin, hair, or shape of head, no racial connection with the Nigritians, who are pure negroes. The Nubians, or, as they call themselves, the Barabra (Berbers) have to look for their kinsmen in the north, and not in the south. The Bedouins of the eastern deserts, the Bisharin and the Ababde, resemble them very much. As regards constancy of types, it is sufficient that no noteworthy changes have taken place within historical times. One of the most important anthropological characteristics is the color of the skin. In the case of the Nigritians, this is practically independent of all external circumstances; air and light have no effect upon it; the negro remains black. Among the northern inhabitants there is an important variability of coloring. Light and air exert a considerable influence upon the color of the skin of the Egyptian and Bedouin. The people of southern Europe also become dark in Nubia, but grow pale again when they return to the north. This fact furnishes the explanation of the diversity of coloring found in the old Egyptian pictures, which were painted according to certain rules, and in which the men appear always dark red, and the women light yellow. The prime color of the one is vermilion, and of the other orange. The former characterizes the man working out in the open air; and the latter, the woman working in the house, and thus preserving her light skin color. Greeks of the third generation living in Nubia have to-day a completely Kushitic appearance. This changeability of the color of the skin characterizes all the peoples as far as Dongola, where the Nigritians first begin, and forms the principal basis for the theory that the north and south of Egypt never belonged to each other ethnologically, and that the northern races of Egypt did not spring from negroes. The direct anatomical proof for this assertion cannot, it is true, be adduced, inasmuch as prehistoric skulls have not been found. Craniological studies point to the near relation of the Egyptians of to-day to the Berbers of Morocco and the Guanches of the Canary Islands.

DICULAFOY'S EXCAVATIONS AT SUSI.—One of the most important archaeological expeditions undertaken in western Asia is that of M. and Mme. Dicufofy, who were sent by the French Department of Public Instruction and of Public Works to Media and Persia to explore the remains of the ancient cities of these regions. Their first expedition was undertaken in 1881 and 1882, and their work was completed in the years 1884, 1885, 1886. The excavations, which were carried out with great difficulty, on account of the fanaticism of the inhabitants, have yielded valuable results from an archaeological as well as from an historical standpoint. The palaces of Artaxerxes and of Darius have been excavated, and it is now possible to reconstruct the plans of these magnificent buildings. The objects collected during these excavations have been transported to Paris, and form one of the most interesting departments of the new galleries of the Louvre. The collections contain polychromic bas-reliefs from the royal palace, representing lion and warriors, and potteries of the first or second century of our era. Besides architectural remains, numerous inscribed cylinders, ivory, bronze, and clay objects have been found. The palace, a model of which is being made, was a magnificent building rising on a platform sixty feet in height, protected by walls, and accessible only on the south side by a large staircase.

ETHNOLOGICAL COMPARISONS.—There are two methods of studying ethnology,—one by studying the growth of a single culture, the other by comparing isolated phenomena among a great number of tribes. While the former yields results of historical interest, the second is of prime importance to the student of psychology, who investigates the laws of the growth of human thought. R. Andree, who has for a long time continued the latter course of studies, has collected a series of essays on "ethnological parallels," most of which have previously been published in various journals. One of the most important results of such comparisons is the conclusive evi-

lence that many similar customs must have originated independently in regions far apart. Among many other phenomena, the author traces the occurrence of masks among various peoples, and shows that they occur all over the world, in America as well as in Australia and all parts of the Old World. It seems that the games in which our children delight are well-nigh universal. The children of the ancient Egyptians played tag; they had balls and dolls. Bodies of dolls were made of wood, and might be mistaken for modern fabrics. Undoubtedly they were dressed by the Egyptian girls, as our girls nowadays enjoy dressing their dolls. There were even movable ones, the hands and feet of which could be moved by means of strings. Others, made of painted wood, were very imperfect in form, and had strings of beads instead of hair. In the museum of Leyden there is an ancient toy that looks as though it had been bought at a Christmas fair. There were figures of animals with movable mouths, and balls of leather. Among Greek and Roman antiquities, dolls made of wood or clay, and others of wax and ivory, are found. Dolls' houses with lead furniture; the saving-box with a slit on top; toy cows, horses, and hogs, — were known to the children of ancient Rome, as they are to our own. From this evidence it might be supposed that our dolls are "descendants" of the ancient dolls; but it must be remembered that there is hardly any people that does not have them. Their use is so general, and so natural to the child, that even the laws of Mohammedanism are disregarded by the childish desire. The Koran forbids representations of human beings, and still the Mohammedan child plays with its doll. The women of Bagdad believe that a doll may eventually come to life, and harm their children, and therefore prevent their use. The girls, however, play with cushions and pieces of wood instead, which they nurse and dress. In Siberia and arctic America ivory dolls, clothed in furs, of beautiful workmanship, are found; in Peruvian graves, dressed dolls of clay are found; and in Africa the girls play with wooden or clay figures. In this way Andree traces numerous ethnological phenomena in their distribution among various peoples, and shows that the human mind everywhere develops on the same lines, and that a migration of inventions must be supposed only in such cases where its existence can be proved by historical facts.

ELECTRICAL NEWS.

Ether, Electricity, and Ponderable Matter.

SIR WILLIAM THOMSON'S presidential address before the English Institute of Electrical Engineers was looked forward to with some eagerness by electricians. The title given above is fascinating, and promises solutions of questions which have been asked for so many years, and whose answer had seemed so hopeless. We think that the address is disappointing. It tells us little that we did not know, and, although suggestive, it hardly points out how to follow the suggestions.

After a few introductory remarks, Sir William dwelt briefly on the necessity of an electrician being also an engineer. He would give a youth desiring to take up the study of electrical engineering a good deal of chemistry, of mathematics, and of dynamics. "I am perfectly sure, that, if the youth is qualified in other departments, the mere addition of electricity to the education of a competent engineer will not take such a long time as might be imagined, and that the merely educational part of the work will not be protracted unduly by adding electricity to the branches learnt in general engineering."

Passing to the main subject of his address, Sir William spoke of the demand that was every year growing in intensity, for something like a mechanical explanation of electrical phenomena: "to know something of the internal relations connected with the wonderful manifestations of force and energy which are put before us in the action of the magnet, in the working even of a common electrical machine, and in electro-magnetic phenomena." The question of the transmission of messages through cables was then taken up at some length, and the history of the theory on which the first Atlantic cable was constructed was given. Sir William then spoke of the two effects which must be considered when an electrical wave is transmitted, — that due to static induction, and that due to magnetic induction. In the first solution of the problem, only the

static effects were considered, since the propagation was so slow that they were large compared with the magnetic effects; but Mr. Heaviside has lately shown that the magnetic induction is really an advantage in signalling or in transmitting speech by telephones, since it makes the dying-out effects much more uniform. If only static induction were considered, the waves of short period would die out more quickly than those of greater length. The magnetic induction helps to make this difference less, and is therefore beneficial.

Taking up the subject of alternating electric currents in wires, the speaker gave some figures on the increase in the resistance of a wire carrying alternating currents as compared with the resistance of the same wire for continuous currents. It has become well known in the last few years that the distribution of a varying current in a wire is not uniform, but the density is greatest near the outside. This has the effect of increasing the resistance; for instance, taking a period of 80 reversals per second, the increase in resistance of a wire 1 centimetre in diameter is not so much as .01 per cent; for a diameter of 1.5 centimetres the increase is 2.5 per cent; for 2 centimetres it is 8 per cent; for 4 centimetres, 68 per cent. For periods of twice the frequency we must multiply by $\sqrt{2}$. The inward penetration of the current into the wire may be compared to the motion of water in a long tube, when the tube is moved backward and forward in the direction of the axis. To represent the case of alternating currents in parallel wires, Sir William would replace the wires by densities of fluid in direct proportion to the electric conductivities, the space around being a fluid without mass, the cylinders of dense matter rotating periodically in opposite directions. To represent the electro-static effect in such a case, "imagine an interface between the two fluids, and give it such stiffness against change of shape as is required to cause it to fulfil the conditions which electro-static knowledge, and our knowledge of the laws of electric and electro-magnetic influence, dictate to us."

Sir William then went on to say that he believed that an electric current actually caused a rotation of the ether, and considered the case of a copper core surrounded by a helix. Induced currents were set up in the copper, and the only action conceivable in the space between the coil and the core was a rotation. This might be either a continuous rotation, or a rotation through an angle proportional to the strength of the current. In iron, however, something quite different must take place. If the fluid whose rotation caused the observed effects moved around continuously, there would be no shearing. If, on the other hand, there were only a drag upon the ether through a certain angle, then there must be a force resisting steady rotation; that is to say, there would have to be an arrangement of such character that a constant torque would produce a constant instead of an accelerated rotation. It would appear that such an effect could only be produced by an inherent rotation of the molecules. To represent a medium of this kind, Sir William imagines a space divided up into a number of small squares, with their sides fixed together by rubber bands. In each a gyrost at in the form of a rotating molecule is placed. Such a medium, without the gyrostats, would represent a perfect fluid; but, with the gyrostats in place, turning could only take place by stretching the elastic bands, which would require a constant force. On this hypothesis, we must suppose that the ether is less rigid in iron than in other metals, and has the same rigidity for all non-magnetic substances. But no model that can be imagined can represent the electro-static as well as the magnetic effects. In concluding, Sir William pointed out that even the very imperfect attempts at a mechanical explanation of electrical phenomena which he had indicated would only apply to a very small part of the subject; and the tremendous difficulties in the way of a complete mechanical explanation prevented him from hoping to see the question solved in his own lifetime, though he felt confident that a solution would be found, and that what appeared so insuperable a mystery to us would be no mystery at all to future generations.

AN ELECTRIC DATE STAMP. — According to *Engineering*, the Electric Date and Time Stamp Company are introducing a new stamp, which at one operation marks on any document the minute, hour, day, month, and year, as well as the usual address and business of the proprietor. Unlike many automatic appliances which are dubbed electrical merely for the purpose of imposing on un-

wary customers, the electric current is really employed in this piece of apparatus. The device consists of five type-wheels with connecting gear, disposed on a single axis; and the minute, the hour, the day, the month, and the year are correctly placed in line under the impression-pad. The minute-wheel is actuated by any clock, through the instrumentality of an electric current, which shifts it round minute by minute, a pawl carrying round the hour-wheel when sixty movements have been made. The apparatus is under trial at the London General Post-Office for dating telegrams.

THE PRODUCTION OF ELECTRIC CURRENTS BY MECHANICAL ACTIONS. — The following interesting experiment is due to M. Siljestroem. Two hollow iron cylinders were closed at one end by the same plate of german silver, and were plunged in ice. They were connected with a galvanometer, and, when the air in one of them was compressed to 86 atmospheres, a current was observed which was in the opposite direction to that which would be produced by an elevation of temperature, although there was a momentary current in the same direction as the latter.

EDISON ILLUMINATING COMPANIES. — The development of the electric-light business is well shown in the holding in Kansas City, on Feb. 12-13, of the semi-annual convention of the Association of Edison Illuminating Companies, a full report of which appears in the *Electrical Review*. The Edison meetings of this kind have invariably been for "business." The policy of President John I. Beggs has always been to hold the convention closely to its work up to the final adjournment, leaving the question of recreation as a secondary consideration. The convention, while not as large as on former occasions in the number of delegates in attendance, was one of absorbing interest, the papers were more numerous and comprehensive than at previous meetings, and there was nothing lacking in the discussions of the vital features of the business with the exception of the unavoidable absence of Mr. Edison and President Johnson, of the Light Company. It was but natural that a sense of exultation at the prospect of speedy results in the fight for the supremacy (which, if the patent laws of the United States mean any thing, are now near at hand) should be evident in all the utterances of the discussions. The cloud of uncertainty which long litigation always brings seemed to be lifted, and a tone of assurance and expectancy was one of the marked features of the session. A paper was read by J. H. Vail, general superintendent of the Edison Electric Light Company, on electric railways and their relations to Edison central stations, illustrating by statistics the advantages to be derived from their operation by Edison illuminating companies. A detailed statement was made by J. H. McClement, comptroller of the parent company, on the progress of the patent litigation. This was supplemented in the evening by a stereopticon entertainment arranged by W. J. Jenks, director of the Standardizing Bureau, showing in a series of slides the history of Mr. Edison's work. An interesting discussion of the results of the use of the Edison chemical meter brought out a paper of great practical interest by E. A. Kennelly of the Edison laboratory, under whose direct supervision experiments have been conducted the past year. The meter has been cheapened both in first cost and expense of maintenance, and samples of new types are now being made for the Paris Exposition. The possible errors, never large under reasonable management, have practically disappeared. A paper on the "Commercial Mean of the Incandescent Lamp," by Mr. Edison, was read by Mr. Upton of the Edison Lamp Company. This set forth in amplified form the practical results of the operation of the laws regarding lamp efficiency brought out some time ago by John W. Howell. It also detailed some interesting facts as to lamp breakage in central stations. The discussions developed the fact that one result of Mr. Edison's experimental work has been to secure fifty per cent more light from the same energy expended, while fully maintaining the guaranteed life of lamps, as a matter of actual record. The other papers were on "Medical Applications of Current from Central Stations," by J. W. Parcell, jun., of the Sprague Electric Railway and Motor Company; "The Steam-Engine," by Professor William D. Marks of Philadelphia; "Inspections," by W. J. Jenks. The executive committee reported in favor of holding the next meeting at Niagara Falls.

NOTES AND NEWS.

It is announced that Great Britain, France, Germany, Spain, Italy, Denmark, the Netherlands, Norway and Sweden, Brazil, Uruguay, Chili, Japan, and the Sandwich Islands have signified their intention of sending representatives to the International Conference which is shortly to be held to consider some means of signalling at sea that will render collisions less liable to occur than under the present system. The proposed conference is the result of a letter addressed to the different maritime powers of the world by the President of the United States, asking their co-operation in this matter. The date and place for holding the meeting yet remain to be fixed.

— Russia's boldness in pushing on her railway system across the Turcoman region to Central Asia has received its due reward. Already the line is declared to be paying its working expenses; and Gen. Annenkoff, the designer, has been encouraged thereby to ask permission of the Emperor to extend the line still farther to Tashkent. In all probability, the request, according to *Engineering*, will be acceded to, because Tashkent, besides being the administrative centre of the province of Turkestan, is a town with a population of 100,000 people, and the extension of the Samarqand section thither would not only tie an important political and trading centre to the Russian railway system, but also link the Syr Daria River and the Aral communications with those of the Caspian. The Aral fleet, as originally established, used to ply on the Syr Daria River, along the banks of which the Russians marched, and founded a series of forts and colonies, in their advance upon Tashkent and Samarqand. The great drawback the steamers had always to contend with was the absence of any fuel except a kind of brierwood known as saxaul. If the Samarqand line were extended to Tashkent, it would cross the navigable head of the river on its way, and be able to provide the steamers with liquid fuel from the Caspian, similar to the supply the railway was able to accord to those on the Oxus when it penetrated to that river a year ago. North of Tashkent stretches a series of steppes, adjoining those of Siberia, which are being gradually settled by colonists from Russia. This region, which is well adapted for agricultural and pastoral pursuits, would benefit considerably by the extension of the railway to Tashkent; so that Gen. Annenkoff has many cogent reasons, besides those of a military character, to adduce in support of his project. It is curious to contrast this activity of the Russians with the lethargy of English authorities in regard to the Indian frontier communications. If the completion of the Quetta line to Candahar would not pay the whole working expenses of the railway from the Indus, it would at least more than pay that on the extension, while adding immeasurably to the security of the Indian Empire. In Burmah again, where Gen. Sir Frederick Roberts, four years ago, urged upon the government the rapid construction of railways as a means of pacifying the country, no important lines, except the slow-paced Tounghoo-Mandalay line, have been taken in hand, and money is being wasted in punitive expeditions against dacoits and tribesmen, which would have been far more advantageously spent on railway-works.

— For paving streets, India-rubber threatens to enter into competition with asphalt. This new pavement, according to the *Engineering and Building Record*, is the invention of Herr Busse of Linden, Prussia, who has introduced it in Hanover. He used it first in the summer of 1887 for paving the Goethe Bridge, which has a surface of about 1,000 square metres, or 10,764 square feet. The new pavement, it is stated, proved so satisfactory that 1,500 square metres (16,146 square feet) of ordinary carriage-way in the city were paved with it last summer. The Berlin corporation, being favorably impressed with the new pavement, has had a large area paved with India-rubber as an experiment, and the magistracy of Hamburg is likewise trying the pavement. It is asserted that the new pavement combines the elasticity of India-rubber with the resistance of granite. It is said to be perfectly noiseless, and unaffected either by heat or cold. It is not so slippery as asphalt, and is more durable than the latter. As a covering for bridges, it ought to prove excellent, as it reduces vibration; but a question may be asked as to its cost. The expense must be heavier than that of any known pavement.

IN A RECENT NUMBER of *Science* we called attention to the danger to which travellers on ocean steamers are subjected when their stateroom companions happen to be consumptives. That this danger is not an imaginary one seems to be demonstrated by an incident which recently occurred in France. A French physician, Dr. Gautier by name, has been investigating the question whether tuberculosis may be communicated by means of its bacilli. That this is possible for lower animals has been thoroughly proved. Dr. Gautier has himself fallen a victim to the disease, having become infected from the pulverized tuberculous sputum with which he was experimenting, thus showing that the disease is equally communicable to man.

WE ARE NOT APT to look to South America for evidence of the greatest progress in science or art, and yet it is said that the sewerage system which is now being constructed in Buenos Ayres is the most perfect in the world. Measures have been taken which will result in putting every house in the city in perfect sanitary condition within three years. Sanitarians will watch the result of this stupendous undertaking with great interest, and will be able to deduce from it many valuable practical lessons.

TO-DAY'S NEED AT JOHNS HOPKINS UNIVERSITY.¹

YOU have doubtless observed, that though this is our annual celebration, when memory and hope are the keystones of a festival, yet there is an undertone of anxiety, an unwonted seriousness in our demeanor and in our words. You know as well as I the cause; but you do not know as well as I the resolution which determines us to turn a temporary loss into a permanent gain. The best financiers can do no better. It is true that we have lost for a time our income from the Baltimore and Ohio Railroad, the securities to which the sagacious founder of the university intrusted his endowment, with so much confidence that he recommended his trustees not to dispose of the stock, but to keep it as an investment. He was doubtless influenced by the fact that this security was free from the taxation which would fasten itself upon another investment.

We believe that this suspension of dividends upon the part of the Baltimore and Ohio Railroad is but temporary, and that the stock is now, and always will be, property of great value. But we have possessions of even greater worth. The Johns Hopkins University owns nearly three hundred acres of land within the present limits of the city, which will soon be laid out in streets and avenues. Fifteen or sixteen miles of street frontage can then be sold or rented. "The past at least is secure;" but to this familiar utterance we can safely add, "the future is as secure as the past." Our cause for anxiety is the present. How shall we make the transit between the prosperity of the past ten years and the prosperity that is to follow? How shall we meet the emergency of the next five years?

There are but three ways, — contraction, borrowing, begging. Contraction brings disaster, borrowing brings a day of reckoning, begging is not pleasant.

It is not agreeable to the managers of a great institution to ask the public to come to their support. It is natural that they hesitate before taking any such step. It is particularly difficult for those who have devoted their lives to the advancement of knowledge and the education of youth, who have renounced aspirations for wealth, who seek for no other preferment than the modest distinctions of an academic life, who are willing that their families should grow up without expectations beyond the inheritance of an honorable name, and who only ask, that, with proper books and apparatus, they may be allowed to continue in the service to which they have consecrated their lives — I say it is especially hard for such persons to ask the public to come to their relief. So it seems to fall upon me, who am not a professor on the one hand, nor a trustee on the other, to say the few frank words which others hesitate to utter.

The situation is this. A prudent management of our affairs during the last few years has enabled the trustees to pay all their current expenses, to build three great laboratories, to collect a large library and a great amount of apparatus, and to buy a great deal of real estate for the buildings that are wanted, and at the same time to lay by a considerable amount of accumulated income. This store they are now spending. It is not, like the widow's cruse, inexhaustible; but if the sum of \$100,000 can be added to it, and if our receipts from tuition remain undiminished, the university will go forward during the next three years without contraction, without borrowing, and without begging. I am happy to say, that although the trustees have not felt willing to make an appeal to the public, and although no authorized statements on this subject have been published, a number of the citizens of Baltimore have, of their own accord, expressed the desire to raise this amount, and have pledged themselves for generous sums. It would be difficult for me to express the encouragement I have received, as one and another of these helpful friends have intimated their readiness to contribute liberally toward the desired amount. More than half of the proposed fund has already been definitely pledged. One subscription has come from New York, another from Liverpool; but almost all, as we might expect, have come from those who are most intimately acquainted with the working of the university, — our own neighbors and friends, who know the difficulties under

¹ Remarks of Daniel C. Gilman, president of the Johns Hopkins University, on the thirteenth commemoration day, Feb. 22, 1899.

which we labor, the methods which we follow, and the hopes by which we are inspired.

A most gratifying sign is the eagerness which young men, whose accumulations as yet are but small, have shown in their desire to come to our assistance. Many such persons are among our own former pupils; others are but lookers-on in Baltimore. I am sure that if it were worth while, the amount still lacking could readily be made up by the contributions of those whose love to their young alma mater is as loyal as that of the sons of Harvard, Yale, and Princeton. Here, for example, is the letter of a Baltimore boy, enclosing a modest check for forty dollars, which, although it is marked "private," I venture to read in part:—

"I can never cease to retain the warmest feelings for my alma mater, for I am not only doubly an alumnus of the university, but am also, by birth, a Baltimorean, and of an old Maryland family, and as such am proud that the greatest American university is to be found in my city and State. I beg, therefore, that you will accept the enclosed check. . . . If you think it desirable, I should be happy to have you call on me for a yearly payment of one hundred dollars as long as the university fails to receive an income adequate to meet its expenses. No one is more keenly sensible than I of the extreme paltriness of this sum. I regret that it is all that I can do; but I can say that if others, equally interested, would contribute in proportion to their income, as I have done with mine, the university would never have to fear pecuniary embarrassment."

But it will not be necessary to ask such aid. The mature and prosperous citizens, who know the conditions of municipal advancement, who know the value of a good name, who know that not money alone has lasting value, but that which money brings in education and refinement, the mature and prosperous citizens of Baltimore, who have received two great gifts from men of New England birth, and two great gifts from an Anne Arundel boy, cannot afford to let an institution that has made the fair name of this city familiar to the scholars of every race and every clime, relinquish in a day of temporary embarrassment the prestige which has been acquired by thirteen years of labor.

GROWTH OF THE AMERICAN ECONOMIC ASSOCIATION.

THE American Economic Association has issued a report, by E. W. Bemis, Ph.D., of its branch associations. Eighteen months ago, Mr. Bemis, as secretary of the first economic branch of this association, reported its success, and urged the organization of similar associations elsewhere. That suggestion has been adopted, and now there are six branches, with over one hundred and fifty members, in the following places: Springfield, Mass.; Orange, N. J.; Washington, D.C.; Buffalo, N.Y.; Galesburg, Ill.; Canton, O.

In view of the great possibilities of growth and influence of these economic centres throughout the country, it becomes important to decide upon a plan of organization. These branches are of three types,—that of Springfield, of Galesburg, and that of Buffalo as at present organized.

The Connecticut Valley Economic Association, organized at Springfield in January, 1886, and now numbering about fifty members, has prospered from the first. This association, like others, is allowed to retain one-half of the three dollars dues for local expenses; and this small sum, thanks to the generous help of the able speakers who have come to Springfield, has thus far covered all expenses. A good room, lighted and heated, is given without charge in the High School building. Similar cheap but suitable places for meeting have been secured in public buildings and private offices by the other branches. Meetings have been held once a month save in summer, and many original contributions to economic theory and investigation have been given which have since seen the light in our economic quarterlies and monographs. A large proportion of these has been given by professors of New England and New York colleges, and by others not connected with the local branch, though six or eight members have also made valuable addresses.

Successful as this experiment has been in many ways, three weak points have been developed: first, a difficulty in securing able lecturers whose regular work would admit of a visit to Spring-

field,—a difficulty less felt in this branch than would be true almost anywhere else, owing to the peculiarly favorable location of Springfield within thirty miles of Amherst and Smith Colleges, and one hundred and thirty miles of Harvard, Yale, Brown, and Columbia, yet a real source of anxiety often to the officers, and one likely to grow from the exhaustion of the field of economic teachers and writers of note within reasonable distance, for it is too much to ask the same person from outside the branch to give his strength often in this missionary work; the second weakness in the Springfield plan lies in the almost inevitable lack of continuity in economic study as long as a different subject is taken up at each meeting; the third difficulty has been the failure of a monthly address, followed by a general discussion, to draw out the resources and greatly stimulate systematic reading in the science of economics on the part of the main body of the members.

That these are sure to prove serious obstacles to success has been proved in Buffalo, where a branch similarly organized a year ago, but cut off by distance from well-known economists, languished, till restored to vigorous life last month in the manner soon to be described.

The branch at Galesburg, Ill., has avoided the difficulties thus far described, but has fallen into one or two others. There the number in the association is limited to twenty-five, elected by the existing members; and no one is allowed to join who does not assume the responsibility of preparing in turn, about once a year, a paper for one of the fortnightly meetings. Further, in order to secure continuity of study, half a dozen or more meetings in succession take up various phases of a single subject, as money, monopolies, the labor question, taxation, etc. By this form of organization much mental development and great interest have been secured; but the limitation of membership and the conditions of admission have kept away a number who would like to join.

The attempt to combine the Springfield and the Galesburg plans has just been made with prospect of success in Buffalo, N.Y., and Canton, O. At Buffalo a reading-circle within the local branch has been formed of all the local members ready to submit to the conditions of admission, which are, attendance, if possible, at every fortnightly meeting, and assumption of the work involved in preparation for the meetings, at which two lines of study are taken up. The first forty-five minutes of each meeting is to be devoted to systematic study of some portion of the general subject assigned for five to eight successive nights: thus, Professor Ely's "Taxation in American States and Cities" is now being studied. Each of the twenty members of the reading-circle reads in advance as much as possible of the chapters assigned for the meeting, and joins in discussion, after two or more members, appointed for the purpose a month previous, and selected in turn from all the members, have given a digest and criticism of the chapters under consideration. The second forty-five minutes is taken up with a review of recent economic articles in twenty-six different American and European magazines, consular reports, and other official publications. One or two of these magazines are chosen for review throughout the year by each member. No constitution for this inner circle has been adopted, but every one who joins does so with a clear understanding of the obligations thereby assumed. The chair is filled each evening by nomination, and the secretary of the general association is secretary of the inner circle. The selection of topics and speakers is in the hands of a topic committee.

This form of organization is too recent to give much ground for forecast; but if the character, ability, and enthusiasm of the members as witnessed by Mr. Bemis the past month be any criterion, excellent results are probable. The Springfield idea of securing for the general membership addresses from outside is adhered to, but no attempt will be made to secure more than four or five such a year.

At Canton, O., about twenty persons, both men and women, as in all the branches, have just formed a branch similar to that as now re-organized at Buffalo, save that in Canton the inner reading-circle, or the active members so called, elect all the officers of the branch from their own number, and admit the associate members to the meetings and discussions, as is not done in Buffalo save on direct invitation of some active member. In Canton the method of work and the conditions of active membership are like those in

Buffalo. In both places local researches in taxation and other economic subjects are also contemplated. The secretary of the Canton branch reports that Professor Ely's "Problems of To-Day" is being studied, and that "the members are enthusiastic."

The branches at Orange, N.J., and Washington, seem to have patterned largely after the Springfield plan.

These suggestions may furnish some help in the solution of the problem of how to extend the work and influence of the association, and form centres of economic study in many parts of our country.

THE WEATHER SERVICE.

THE popular dissatisfaction with the weather predictions as now furnished by the Signal Office has become so great, that a thorough discussion of what is best to be done to improve the service is certainly desirable. Such a discussion has been taking place in the columns of the *Boston Post*, and from that paper we here quote from a recent letter of Mr. H. H. Clayton of the Blue Hill Meteorological Observatory, Readville, Mass. In an editorial note the *Post* seems inclined to doubt the wisdom, if not the truth, of the sweeping assertion of the inefficiency of a large part of the Signal Corps made by Gen. Greely in his recent report to Congress, and it was this which called forth Mr. Clayton's letter in which he takes the following ground.

"Gen. Greely may possibly not be right in his specifications as to exactly what persons are inefficient, but any one who has studied the history of our weather service in comparison with that of foreign countries can scarcely doubt but there is great inefficiency somewhere in our service; and it seems right to allow Gen. Greely every assistance possible to improve the service, until there is proof that his efforts are in the wrong direction. The financial support and the facilities afforded our signal service are the best in the world, and it has been a continuous surprise to the writer that its efficiency has not been greater. The following figures show in round numbers the amount of money appropriated by various governments in Europe and America for the support of their weather services: United States, \$900,000; Great Britain, \$80,000; Germany, \$56,000; Russia, \$65,000; Austria, \$10,000; Switzerland, \$6,000; France, \$40,000. This estimate for France does not include the cost of observations made at a few astronomical observatories and mountain stations, which may perhaps increase the total amount expended by France to \$60,000. It is thus seen that the amount of money appropriated for its weather service by the United States is ten times greater than that of any country in the world, and is greater than the amount appropriated by all of the governments of Europe combined, including Italy and others not mentioned above.

"In Europe a large part of the observers are voluntary observers, or they are men who are engaged in other pursuits, and for a small compensation take meteorological observations, and telegraph them to the central stations. For this reason it has been necessary to adapt the observations somewhat to the convenience of the observers, and it has been impossible to obtain all over Europe a system of simultaneous observations such as are obtained in the United States. The principal set of observations in the different European countries is taken all the way from 7 A.M. to 9 A.M.; and on account of the difficulty of arranging codes, and transmitting telegrams from one country to another speaking different languages and having different interests, it is almost noon before the morning observations are in an available form in the different countries for use in making weather predictions, while in the United States it is but little more than an hour after the observations are taken before they are available for use at the central office. Again, owing to their small appropriations, none of the European countries have been able to obtain extensive reports more than once a day from surrounding countries, and thus form a set of relatively complete weather maps, such as was previously done three times a day in the United States, and is now done twice a day. The full weather map made by the European weather services is from the morning reports taken between 7 and 9 A.M., though most of the services make supplementary maps from less complete reports received in the afternoon and evening.

"So far, it is seen, then, that our weather service is better equipped, and with far better facilities for effective work, than any service in the world; but what are the results? In 1881 the per cent of verification of their weather predictions estimated by the French meteorological office was 82. Since then it has steadily risen, until, in 1888, a verification of 90 per cent was claimed. In the same manner the per cent of success estimated by the London office for Great Britain has risen from 78 per cent in 1882, to 83 per cent in 1887. In Germany the per cent has risen from about 80 per cent ten or twelve years ago, to 88 per cent in 1887. According to the official verifications of our signal service, the per cent of successful weather predictions rose from about 82 per cent in 1875, to 89 in 1883, and then decreased irregularly to 74 per cent in 1887, or 81 per cent when corrected for the greater interval covered by the predictions. These signal-service verifications for different years are not strictly comparable, because they were verified according to varying rules and with different degrees of care; but the signal service uses them so, and the figures at least agree with the general impression that there has been no increase in the accuracy of the signal-service predictions during the last fifteen years. Neither are the per cents of verification for one country comparable with another, since many of them were verified by different rules; but the results are comparable among themselves, and the steady increase of accuracy claimed for the European weather predictions is no doubt a fact. The able papers and investigations proceeding from the members of the European bureaus seem sufficient evidence that great thought is being given to the improvement of meteorology, and the advance of meteorological knowledge is undoubted.

"The great difficulty with our bureau seems to have been that Congress made it a military rather than a scientific organization. Several years ago a committee appointed to investigate the bureau recommended that it be transferred to a civilian organization, either gradually or suddenly. The National Academy of Science, when consulted on the subject, recommended the same thing; but for some reason unknown to the writer, Congress has neglected or refused to make such a transfer, and last year struck out a clause to that effect in the agricultural bill. There is scarcely any doubt, that, with some scientific investigation, certain of those storms might have been predicted which in recent years have struck our coast unheralded by the signal service, and left wreck and ruin behind,—notably the storm of Jan. 9, 1886, for which no signals were ordered, and in which it is estimated that about 125 vessels were wrecked on the New England coast. Were the weather service of our country in the hands of well-selected scientific men, it would undoubtedly become, as it ought to become with such splendid facilities as it now has, one of the finest meteorological bureaus in the world. If, however, this cannot be, it is hoped that every facility will be furnished Gen. Greely to make it an effective military organization. Gen. Greely's recent books and excellent 'Report of the Lady Franklin Bay Expedition to the Arctic Regions' indicate a deep interest in and a knowledge of the needs of meteorology, and he is no doubt sincere in his efforts to increase the efficiency of the Signal Corps.

"Besides the re-organization of the bureau, an immense advance might be made by organizing local predicting bureaus, where the predicting officers could make a closer study of the conditions surrounding them, and gain more time for prediction, instead of, as now, being compelled rapidly to make predictions for almost the entire length and breadth of our land, which is many times larger than any country of Europe, except Russia. The favor with which the Blue Hill predictions, as well as those of others in this and other parts of the United States; have been received, seems proof that local weather bureaus would be at once appreciated by the public."

MENTAL SCIENCE.

The Genesis of Error.¹

PROFESSOR S. EXNER of Vienna contributed to the Congress of German Naturalists and Physicians a very suggestive essay upon the principles underlying the origin of illusion in man and the ani-

¹ From the *Revue Scientifique*, Jan. 12, 1889.

mal world. The physicist, he observes, before deducing any result, takes into account the errors of his instruments. The scientist is always working with one certain instrument, the human mind. The errors of this ever-present factor in all work form a most important field of study.

In the study of instincts, such as those that direct birds in the building of their nests, insects in the formation of their communities, we often admire the wonderful resemblance of these complex acts to the results of reason. And yet we recognize an important distinction between them: their sphere is limited, their power of adaptation to new conditions is small. It is a remarkable mechanism, but has application to a limited number of movements. A bird shows remarkable skill in weaving the threads with which it builds its nest, fastening it to the limb of a tree, and adapting it to the shape of the twig. But tie the foot of a bird in a cage, and it cannot make use of its skill in weaving to untie the fastening, but struggles and flutters until it kills itself or is accidentally freed. Teleologically speaking, certain adjustments are ingrained in its nervous system; but these adjustments are special, not general. The more perfect the instinct, the more stable and invariable is it; the less rigidly the adjustments are ingrained, the more does the act resemble what we term "reason." Diversity and adaptability are the marks of rational development. The weakness of animal intelligence is always in the lack of ability to break away from routine associations; to proceed from two facts to a third. A dog will defend himself if you tease him, but he will not bite. He knows how to use his teeth well enough with his fellows, but towards man he has acquired an attitude of deference.

Animal instincts result from the environment, and must be judged in the environment. When looked at from a human standpoint, these actions seem foolish and irrelevant. We, too, have our rigid instincts, our reflex actions. The closure of the eyelids when an object threatens the eye is a useful protective mechanism; but when we are to undergo an operation, it may be harmful. None the less all the strength of the will is incompetent to keep the eye open. It acts according to its acquired habits. It is true that we are conscious of our error, which animals are probably not; but this is not an essential point. It is proposed to show that the typical kinds of error arise, as do these misapplications of instincts, from the unwarranted application of a general rule to a particular case.

The majority of sense-deceptions support this view. Irritation of any part of the retina arouses a sensation localized in space where an object causing such an irritation would ordinarily be found. In some cases we are freed from illusion by the remembrance of former experiences. Savages are apt to mistake an image in a mirror for a real object behind it: repeated experience allows us to see the image as an image in the plane of the mirror.

Here it is easy to distinguish between the sensory and the memory factors, but in some cases this may be difficult. If you draw a line on a sheet of paper, and cover it up with a second sheet so as just to conceal the end of the line, and show it to some one ignorant of the arrangement, he will be greatly surprised not to find the entire line longer than it is when you remove the second sheet. He does this because it is an uncommon experience to have so little of a line covered up. He cannot help forming a prejudice on the basis of what is most probable. Is this an error of sensation, or of memory?

There are a host of similar deceptions. One need only refer to the tricks of the conjurer. He takes care to appeal to something true as a rule, but false in this particular case. Again: he directs his gaze towards his right hand, infallibly carrying the eyes of the observers to the same spot, while he is performing the trick with the unobserved left hand. Ordinarily we direct our attention to the point of the field of vision in which an action is going on, and we erroneously follow this rule when we should not. We are mechanically obey the general rule as we close our eyelids when an object threatens us.

The illusion consists in the observation of the general to the exclusion of the special. A high intelligence consists in the command of a wealth of associations, and thus a power of distinguishing between the two. A typical instance is that of the host of persons who religiously record the numbers drawn at the lottery, reasoning,

that, inasmuch as all numbers have an equal chance of being drawn, numbers not drawn now must have a greater chance of being drawn later on. In all games of chance one hears the same argument. The luck must change: good fortune must be followed by bad, and *vice versa*. This common error, again, consists in overlooking the particular case; for while, in many cases, such reasoning would be entirely correct, in the case of the lottery and of games of chance it does not hold, because the numbers are all replaced, the cards newly dealt after each issue, thus making the chances of every lucky event just the same as before. It is a confusion of the case in which the ball is returned to the urn with the more frequent cases in which it cannot be returned. Of the same character is the belief in the luckiness or unluckiness of certain players; in the argument, that, because a person has happened to receive more than a normal share of lucky turns, he has a right to expect the continuance of such luck; or, again, the fancied relations between the weather and terrestrial events, etc.: in short, in many kinds of superstition.

More refined examples of the same kind of error can be found in the fields of art and science. When an architect supports a balcony upon two slender iron pillars, it does not appear pretty, because of the disproportion between the supports and the object supported. The origin of this judgment is to be traced to the fact that we have comparatively little experience with the strength of iron, and much experience with the weight of stone. In general, the impression of solidity carries with it the sentiment of beauty; while the use of iron, however convincing the calculations of the architect, does not carry with it this impression. In various forms of art we see the same association between the form and the material used. Our traditions and the experiences of the race thus play a *rôle* in our sentiments, and are a factor in the genesis of error. The Greeks built temples of marble in a style derived from times when wood was the building-material. Returning to science, we may examine the famous argument of Zeno for illustration of our main thesis. Achilles cannot overtake the tortoise if the latter is at all ahead of him, because, while Achilles makes up the distance, the turtle has advanced beyond it; and so on. We get the impression of infinite space by the infinite aggregation of finite spaces, because ordinarily such a sum would be infinite; but here the spaces tend to the infinitely small, and so their sum to a finite quantity. In spite of the ages of discussion spent over this problem, it still remains a real source of error; and from this puzzle of Zeno, down to the blind action of a humble animal, one can trace the genesis of error as a faulty application of a general law to a special case; as the instinctive action of an ingrained nervous adjustment to an environment different from the normal.

ABNORMAL SENSE-ASSOCIATIONS.—Increased attention has recently been given to a class of sensory associations of rare occurrence but extremely interesting. When a certain part of the body is hurt, some persons simultaneously feel a pain in a distant and disconnected part of the body: to these the name of "synalgia" has been applied. They are idiosyncrasies, and are of various kinds. So, too, there are "synaesthesias," or cases of an irritation in one place causing a sensation in another. Dr. Fromental brings these into line with the common experience of sneezing in response to a glaring light stimulation. He does not regard this as reflex, but thinks it psychic in character, and due to the irradiation of a disturbance in the cortex of the brain. The explanation ascribing the connection to an anastomosis between various nerves is also rejected. The peculiar case of hearing colored sounds would also be susceptible to the same explanation. They would be more or less present in all persons, but would only be striking in peculiarly nervous individuals.

BOOK-REVIEWS.

Physical Realism. By THOMAS CASE. New York, Longmans, Green, & Co. 8°.

THIS work contains a criticism of philosophical idealism, or subjectivism, together with the presentation of a new theory which the author offers in its stead. According to the view of Berkeley and his followers, the external world of material things has no real existence, what we call a body being in fact nothing but a cluster of

ideas and sensations in our minds. This theory Mr. Case holds to be contradicted by physical science, which reveals to us certain objects, such as the waves of light, for instance, which are not and never can be objects of sense, but which are nevertheless known to exist. He takes up the works of the leading idealists, and makes an elaborate criticism of their views and of the arguments by which they sought to support them; and this part of his work contains much interesting and useful matter. He rightly regards Descartes as the real founder of idealism, because he assumed that the immediate objects of knowledge are ideas, although he endeavored to reach a knowledge of the external world by inference. This fundamental assumption of Descartes, which has been repeated by every idealist since, is justly treated by Mr. Case as a begging of the whole question; and the passages in which he criticises it are the best in the book. He does not confine his strictures to this one point, however, but deals also with Hume's theory of belief and association, Kant's doctrine of necessary truths, and other topics more or less nearly related to the idealistic view. Some of his remarks, especially on the subjects of induction and necessary truth, seem to us quite as doubtful as those he criticises; but the whole of this portion of his work is well worthy of attention.

Mr. Case has not confined himself, however, to criticism, but has presented a theory of his own in place of the one he criticises; and with regard to this we are obliged to dissent from him. Rejecting idealism as he does, he equally rejects the natural realism of the Scottish school, and maintains that the object of sense-perception is neither an idea nor a body outside of us, but an affection of our nervous system. "The sensible object," he says, "is the nervous system itself sensibly affected. The hot felt is the tactile nerves heated, the white seen is the optic nerves so colored" (p. 24). And again: "I perceive my nervous system, not so far as it is nervous structure moving, but so far as it is sensibly affected in different parts, the optic nerve so far as it is visibly white, the gustatory nerve so far as it is sweet to taste, and so on" (p. 151). Now, we think most people will deny this assertion outright. This reviewer, certainly, is not conscious of perceiving his own nerves sensibly affected, and it was only by studying anatomy that he learned that he had nerves. Besides, what does Mr. Case mean by calling the nervous system, as he repeatedly does, an "internal" object? "Internal," with reference to this question, means "in the mind;" and "external," "out of the mind;" and therefore my own nervous system is just as truly an external object as is the farthest star that I can see. For these reasons we cannot think that Mr. Case has solved the problem of perception.

The Development of the Intellect. By W. PREYER. Tr. by H. W. BROWN. New York, Appleton. 12°.

SOME weeks ago we referred, on its appearance, to the first portion of Mr. Brown's translation of Preyer's great work, "Die Seele des Kindes," and expressed our gratification that it satisfactorily presented to the English reader the results of the Jena physiologist's researches in the field of child-psychology.

The second part, which is before us, is equally well done, and it fully sustains the reputation of the International Education Series, of which it forms Volume IX. A conspectus of Professor Preyer's results, prepared by the translator, greatly increases the value of the book to the average teacher and to the ordinary reader.

The author sees in the power of language and its development the safest and best guide to the tracing of intellectual development, and he traces the growth of this power with great caution and fullness of knowledge. We cannot in this brief space attempt to condense the argument of the book: we must be satisfied to repeat substantially what we said of "The Senses and the Will:" it is a safe companion for any teacher in her study of the unfolding of a child's mental power, and a stimulus to further research and investigation.

Political History since 1815. By CHARLES H. LEVERMORE and DAVIS R. DEWEY. Boston, W. J. Schofield. 8°. \$1.25.

THIS book is an abstract of lectures delivered in the Massachusetts Institute of Technology: hence it is hardly adapted for reading, but it will serve admirably as a guide to historical students, and also to refresh the memory of those who have studied. It

covers the political history of the whole world since the fall of Napoleon, with the exception of the United States, the history of our own country evidently being a separate study in the institute. The selection and arrangement of topics in the book seem excellent; and we are particularly pleased with the small attention given to military affairs, which in some books called histories overshadow every thing else. The opening lecture treats of the various races, governments, and religions of the world; and the remainder of the work presents the recent history of the various nations separately, beginning with England and her empire, and ending with the African continent. The dates of important events are given, and some statistical matter is introduced. A bibliography of the subject is given, and special authorities are cited on all important points. The book is well and carefully printed, and must, we should think, be very useful to students of the field it covers.

Shall We Teach Geology? By ALEXANDER WINCHELL. Chicago, S. C. Griggs & Co. 12°. \$1.

IN this work Professor Winchell sets forth the claims of his favorite science to a more prominent place than it now holds in general education. He first inquires what education is, and comes to the conclusion that it includes both the training of the faculties and the acquisition of useful knowledge. He has an excellent chapter on the faculties themselves; and, while admitting that some of them are better developed by literature or mathematics, he insists that no study will develop them as a whole better than geology. Like most physical scientists, he is severe on the study of languages, especially of Greek and Latin; and, so far as the mere languages themselves are concerned, we incline to agree with him. But language is the medium of literature; and Professor Winchell seems to show an inadequate appreciation of literature, and of the moral and intellectual culture that it gives. But the principal defect of his work is its ignoring of the mental and social sciences. He seems hardly aware of their existence; for he mentions none of them but history, and mentions history only to slight it, declaring that it trains no faculty but verbal memory. His disparagement of history is peculiarly unfortunate, for history is to the evolution of man what geology is to the evolution of the earth and its flora and fauna; and it is surely as important for us to know how man has come to be what he is as to know how the earth's crust has come to be what it is. To this reviewer it seems that the most important study at the present day is that of man, his nature, his duties, and his history; and if this is so, it is hardly possible to give geology so much attention as Professor Winchell desires: for he is not satisfied with a year's study or so, but would have the subject taken up in the primary schools, and pursued every year as long as the student attends school. When we consider that geology is only one science out of fifteen or twenty, and when we further consider the importance of literature and the need of learning foreign languages early in life, it is evident that we cannot give so much time to geology alone. Nevertheless, we are glad to see the claims of the science so well presented, and we hope Professor Winchell's book will be read by educators everywhere.

A Historical Geography of the British Colonies. By C. P. LUCAS. Vol. I. Oxford, Clarendon Pr. 12°. \$1.25.

WE noticed some time ago the little volume introductory to this work, and we are now glad to receive the first volume of the work itself. It contains a little less than two hundred pages, and treats of the European dependencies of Great Britain, and the minor dependencies in Asia and the Indian Ocean. In preparing the work, Mr. Lucas has had the assistance of various persons connected with the governments of the colonies in question, and the portions relating to Malta and Cyprus have been mainly written by one of his associates in the Colonial Office. The work has been prepared with care, and contains a large amount of information in comparatively small space. Each dependency is treated separately, while at the same time their relations to each other and to the home government, and their importance to the empire, are duly pointed out. The history of each is briefly recorded, and sometimes, as in the case of Malta and Cyprus, it makes interesting reading. Then the main geographical features are described, and an account is given

of the people and the mode of government. Most of the colonies, or dependencies, dealt with in this volume are valuable chiefly as naval and commercial stations, this being particularly the case with Gibraltar, Malta, Aden, Singapore, and Hong Kong; but others, such as Cyprus, Ceylon, and Mauritius, have inherent resources of their own. The work shows the immense variety of races, religions, and material interests with which the British Colonial Office has to deal; and this notwithstanding none of the larger dependencies are touched upon. Germans in Heligoland; Spaniards, Italians, Greeks, and Turks in the Mediterranean; Arabs, Negroes, Indians, Malays, and Chinese in the Eastern seas,—all pass in review before us; while the three great religions of the world,—Christianity, Mohammedanism, and Buddhism,—besides minor faiths, are represented. If the work is completed on the plan of this volume, it will be useful not only to geographers, historians, and statesmen, but to all intelligent persons who wish to be informed about the world's affairs.

AMONG THE PUBLISHERS.

ROBERT CLARKE & CO., Cincinnati, O., announce the fifth edition of "Benner's Prophecies," with forecasts for 1889, 1890, 1891. These prophecies are of future ups and downs in prices, and what years to make money on pig-iron, hogs, corn, and provisions, by Samuel Benner, an Ohio farmer.

—The following are from the contents of the *Popular Science Monthly* for March: "New Chapters in the Warfare of Science," by Andrew D. White, LL.D.; "The Chemistry of To-Day," by Professor Ira Remsen; "Glass-Making," by Professor C. Hanford Henderson; "South Slavic Moon-Myths," by Dr. Friedrich S. Krauss; "Competition and the Trusts," by George Iles; "Law as a Disturber of Social Order," by Benjamin Reece; "Among the Fiji Islands," by Coutts Trotter; "The Foundation-Stones of the Earth," by Professor T. G. Bonney; "Natural Science in Elementary Schools," by J. M. Arms; "The Aryans in Science and History," by Horatio Hale; "The Americanists in Congress;" "Sketch of Pierre Belon" (with portrait); also the regular correspondence and editorial departments, literary notices, popular miscellany, and notes.

—The *American Journal of Archaeology*, Vol. IV. No. 4 (Boston, Ginn & Co.) contains "Inedited Terra-cottas from Myrina, in the Museum at Constantinople" (with 2 Dujardin heliotype plates), by Salomon Reinach; "Discoveries in the Attic Deme of Ikaria," by Carl D. Buck, and "A New Sikyonian Inscription," by Mortimer L. Earle, both members of the American School of Classical Studies at Athens; "Early Bronzes discovered on Mount Ida in Krete" (with 5 plates and 4 figures), by A. L. Frothingham, jun., professor of archaeology at Princeton; "Remains of an Ancient Greek Building discovered in Malta" (with ground-plan), by A. A. Caruana, director of education in Malta; notes on the excavation of a Christian palace at Rome, and the existence of America known early in the Christian era; reviews and notices of books on archaeology—general, Oriental, classical, Christian, and prehistoric— and on the Renaissance; archaeological news from Asia Minor, Austria-Hungary, Central America, Colombia, Denmark, Egypt, England, France, Germany, Greece, Hindustan, Italy, Krete, Kypros, Palestine, Phœnicia, Russia, Sicily, Spain, Syria, Tunisia, Turkey, United States, and Wales; and summaries of archaeological periodicals.

—William H. Burnham, Ph.D., late fellow of Johns Hopkins University, will give in the March *Scribner* some valuable practical suggestions to busy men for economy in brain-work.

—The *Contemporary Review* for March (New York, Leonard Scott Publishing Company) will contain an important paper on the Panama Canal by the eminent traveller, Mr. Edward Wymper, illustrated by a large chart of the scene of operations, etc. An interesting and full *résumé* of the financial condition of the Canal Company appeared in the *Nineteenth Century* for February, 1888, which is particularly valuable, in view of the recent collapse of the enterprise.

—Probably the most interesting paper in the *Scottish Review* (New York, Leonard Scott Company) for the present quarter is a translation of Ivan Turgenieff's weird story of the "White Lady."

The spirit which forms the central figure in this extraordinary play of the imagination belongs to a class which appears more frequently in the popular beliefs of Russia than in those of other countries. It is, however, not unknown in Scotland. Sir Walter Scott's ballad of "Glenfinlas," for example, is based upon a legend of a young man killed by a being of this sort,—a catastrophe which Turgenieff has obviated or postponed by the use of a peculiar expedient.

—No less than eight editions have been called for of the *Contemporary Review* for February, containing the remarkable article on the Bismarck dynasty. This article is said to be circulating freely in Germany.

—"England and Germany in East Africa" forms the subject of the opening paper in the *Fortnightly* this month. Professor Dowden writes on "Hopes and Fears for Literature;" Mr. Swinburne continues his notice of Victor Hugo's poetry; Professor Tyndall furnishes another instalment of his articles on "English Light-house Management;" Dr. Ingram writes on "Two Centuries of Irish History;" and Mrs. Lynn Linton begins her series on "Characteristics of English Women." Among the other articles, the unsigned one on the "Trade of Author" will probably attract most attention.

—The February number of the *Modern Science Essayist* contains "Solar and Planetary Evolution," an essay by Garrett P. Serviss, together with criticisms on the essay by R. G. Eccles, M.D., Professor Van der Weyde, and L. G. James, M.D.

—The "Truth Seeker Annual" for 1889 contains a fine picture of the statue of Giordano Bruno, soon to be erected in Rome, and two illustrations showing the Lick Observatory and its great telescope.

—During the session of the Electric Light Convention at Chicago last week, the *Western Electrician* issued a daily edition, containing full reports of the proceedings.

—Col. T. W. Higginson's poems, which Longmans, Green, & Co. are about to publish in New York and London, are dedicated to J. R. Lowell, "schoolmate and fellow-townsmen." The volume is called "The Afternoon Landscape," for the morning of the poet's life is now past. The poems include the sonnet to "Duty" and the lighter stanzas on "A Jar of Rose-Leaves." Among the translations are Sappho's "Ode to Aphrodite," and a dozen sonnets from Petrarch and Camoens.

—"Micah Clarke: his Statement" is the title of an autobiographic tale of Monmouth's rebellion, which is soon to be published by Longmans, Green, & Co. It is rather a narrative of personal adventure than a romance, yet the author's art recalls both "Lorna Doone" and "Kidnapped." This is a tale of adventure, full of strong incident and vigorous character-drawing, with not a little incidental humor. Saxon is a younger brother of Dugald Dalgetty, and quite as delightful in his professional pride.

—The *Political Science Quarterly* for March opens with a striking article by H. L. Osgood, upon "Scientific Anarchism," reviewing the theories of Proudhon, and showing the aims of American anarchists. Professor Gustav Cohn of Göttingen, taking the progressive income taxes of Switzerland as his text, indicates the merits and the dangers of this democratic scheme of taxation. Mr. Arnold Forster (son of the late Irish secretary) presents forcibly the Unionist view of the Irish question. A conservative Frenchman, M. Gauvain, explains the causes of the present crisis in France, and the significance of "Boulangism." Mr. Bernheim sketches the history of the ballot in New York, and argues for the Australian System. Professor Woodrow Wilson analyzes and criticises Bryce's "American Commonwealth." The June number will contain an article by Professor Sloane of Princeton, editor of the *New Princeton Review*, and will continue and bring down to the 1st of May the "Record of Events" heretofore published in the *New Princeton Review*.

—W. J. Schofield, 105 Summer Street, Boston, Mass., has published "Political History since 1815 (excluding the United States)." This syllabus of lectures upon modern political history, prepared originally for use in the Massachusetts Institute of Technology, by C. H. Levermore, assistant professor of history, and D. R. Dewey,

assistant professor of economics and statistics, presents a skeleton of nineteenth century history down to 1889, and is based on copious references to standard works, and to important articles in the leading reviews.

— John Delay, New York, calls attention to the fact that the volumes in his new library of Gleanings from Foreign Authors are to be published at 30 cents, instead of 50 cents as previously advertised.

— Apropos of the arrival in the American market of his "Souvenirs d'un Homme de Lettres," it is said that Daudet is suffering from a hopeless nervous malady of the kind which wrecked Heine's life, and it is feared he may not be able to accomplish much more work.

— Mr. Ivan Panin, Wellesley, Mass., will print his lectures on Russian literature, delivered before the Lowell Institute, Boston, in a style uniform with his translations from Pushkin, as soon as he procures enough subscribers at \$2 per volume. Names should be sent to the above address before April 1.

— *The Publishers' Weekly* announces that Mr. Samuel C. Eastman of Concord, N.H., while spending the summer in Denmark, translated, under the author's encouragement and supervision, Dr. George Brandes' "Impressions of Russia." Dr. Brandes was invited to deliver a course of lectures in French before the literary clubs of St. Petersburg and Moscow, and while there he was given remarkable facilities for studying the people and institutions of the country. His views are extremely lively and entertaining, and his frankness of criticism is so pronounced that the book was placed on the black list by the censor. The chapters on Russian literature are fresh and full of information, and the work is a decided addition to our knowledge of an extraordinary country. Mr. Eastman's translation will be shortly published by T. Y. Crowell & Co.

— The *Forum* for March begins its new volume with an article by Cardinal Manning, showing the evils of compulsory education, and opposing the reading of the Bible in the public schools. Dr. George P. Fisher of Yale University will write a refutation of Cardinal Manning's conclusion. A paper by Professor W. S. Scarborough, a negro, will explain the aspirations and hinderances of the negro in the South.

— Peter Paul & Brother, Buffalo, will publish immediately "The Champions of Agrarian Socialism, and their Teaching," from the German of the Rev. V. Cathrein, S.J.

— Brentano Bros. announce that they will publish shortly "Where the Trout Hide," giving a detailed description of a newly opened, easily accessible, and beautiful country, whose waters teem with brook trout, black bass, and land-locked salmon, by Kit Clarke, an angling enthusiast.

— It is said that Mr. Du Chaillu's book on the Norsemen has practically been reset for the sixth time, the author having made discoveries and revisions which involve important changes and additions. The whole work, which has 1,200 beautiful illustrations, will probably appear next month.

— A volume which promises to be of interest to Scotsmen and their descendants in this country will shortly be issued from the office of the *Scottish American*, New York. It contains a series of essays illustrative of Scottish life, history, and character, gathered together under the title of "Scotland and the Scots." The author, Mr. Peter Ross, has long been a diligent student of the history of the Scottish race on this side of the Atlantic; and in the opening essay, "The Scot in America," is given a succinct account of how the people of that nationality have aided in all the religious, military, educational, national, political, and other movements which make up the history of North America. Among the other essays are "The Scot Abroad," "Scottish Characteristics," "Scottish Sports," "Scottish Superstitions," and "Freemasonry and Robert Burns."

— J. B. Lippincott Company have in press the third revised and rewritten volume of "Chambers's Encyclopædia," which will be complete in ten volumes; a "Life of Henry M. Stanley," by Rev.

H. W. Little; and "Examples, Rules, Tables, and References" for engineers, etc., by John Richards (subscription). They will also add to their medical list a "Cyclopædia of Diseases of Children," edited by Dr. J. M. Keating, to be in four volumes, sold by subscription; a new edition of the "Elementary Treatise on Human Anatomy," by Professor Joseph Leidy; "The Clinical Diagnosis of Non-Surgical Diseases," by Dr. Rudolf von Jaksch of Vienna, translated by Dr. Cagney of London; and a fifth volume in their "Practical Lessons in Nursing," devoted to "Diseases and Injuries of the Ear."

— A. Flanagan, 185 Wabash Avenue, Chicago, has issued a game of cards entitled "Literary Whist, or, Games of Great Men," prepared by N. O. Wilhelm. In playing the dozen or more games that may be played with these cards, it is expected that one may soon become acquainted with the lives, the works, and the characteristics of the world's greatest poets, prose writers, statesmen, warriors, scientists. Most of the games are simple enough for a child, or may be made abstruse for the learned. The set consists of 100 cards, $3\frac{1}{2} \times 2\frac{1}{2}$ inches. There are 26 "books" to be made or obtained. These are of poets, indicated by key-word P.; prose writers, key-word P.W.; soldiers, So.; statesmen, St.; scientists, Sc. Contemporaries of the same class are in the same book. Prominent traits and works are given with each name, so that in playing these games one acquires valuable knowledge while passing away a pleasant hour.

— Dr. H. A. Hare of the University of Pennsylvania has issued through P. Blakiston, Son, & Co., Philadelphia, his essay on "Mediastinal Disease," to which the Medical Society of London awarded the Fothergillian medal for 1888.

— Henry Worthington, 88 Liberty Street, this city, announces that he will furnish free, upon application, a handsomely illustrated catalogue descriptive of steam-pumps, pumping-engines, and hydraulic machinery.

— We learn from *Engineering* that the long-continued experiments which have been conducted on board the "Nettle" at Portsmouth, with the view of determining the respective merits of compound armor and of solid steel armor as a protection for battleships, have just been brought to a close. Only two Sheffield manufacturers sent in compound samples for competition; but the number of steel plates forwarded for trial amounted to eight, from as many makers, being two less than were expected. The ten-inch plates were attacked by steel and Palliser projectiles, at a range of thirty feet; and although two of the solid steel armor-plates, at least, underwent the crucial ordeal with satisfactory results, the superiority remained with the steel-faced armor now adopted in the English Navy.

— In experiments recently made in France on the elasticity of cork, it was found that disks of that substance, when submitted to a pressure of 1,100 kilograms per square centimetre, were compressed to one-fifth their thickness, and recovered their original dimensions in exactly ten minutes after the pressure was removed.

— The announcement recently made, that Professor Kruss of Munich had succeeded in decomposing nickel and cobalt, proves to be erroneous. What he has really done is to obtain from these two elements a third one, which existed in them as an impurity.

— In the March *Atlantic*, history is possibly the strong point, there being a paper on those two brave Scots, "The Keiths," by Hope Notnor, and one of Mr. Fiske's papers upon "Ticonderoga, Bennington, and Oriskany." Mr. Frank Gaylord Cook writes an article upon "Some Colonial Lawyers and their Work;" while a theme of a more recent day is treated in "Personal Reminiscences of William H. Seward," by Samuel J. Barrows, and his wife Isabel C. Barrows. The paper is especially interesting, since Mr. Barrows was private secretary to Mr. Seward, and Mrs. Barrows also acted temporarily in the same capacity. In this connection, Stuart F. Weld's consideration of "The Isthmus Canal and our Government" should be mentioned, and a review of Professor Bryce's book on "The American Commonwealth." Mr. James's serial, "The Tragic Muse," abounds in studies of personality, and Mr. Hardy's "Passe Rose" is interesting. The first part of a negro story called

"Hannah Calline's Jim," and an essay on "Simplicity," by Charles Dudley Warner, close the prose articles; and the poetry includes Mr. Whittier's "The Christmas of 1888," and verses by E. Wilson.

LETTERS TO THE EDITOR.

* * *Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith.

Twenty copies of the number containing his communication will be furnished free to any correspondent on request.

The editor will be glad to publish any queries consonant with the character of the journal.

The Soaring of Birds.

SINCE my paper was reported in *Science* (xii. p. 267), Messrs. Oliver, Pickering, and MacGregor have favored the journal with letters on the subject.

Professor Oliver (xiii. p. 15), while admitting that the action I suggest is to some extent efficient in sustaining the bird, questions its sufficiency. I had asked the same question myself, and found no answer; but I am glad to know, through private correspondence, that Professor Oliver and at least one other physicist are disposed to put the question to nature through experimentation.

Professor Oliver also suggests minute vibratory motions of the wings, or perhaps of the individual wing-feathers, and cites an observation by another. The same hypothesis was advanced in explanation of the allied phenomenon of hovering, but was rejected on the strength of what seemed sufficient observation (*Nature*, viii. p. 324; ix. p. 5). The hovering bird remains in one place for so long a period that he can be deliberately and carefully watched.

Mr. Pickering and Professor MacGregor each proposes an explanation different from mine, and not involving differential air movements, but appealing instead to a homogeneous and uniform wind. Their conception of relative velocities is so different from mine, and I am so confident in the correctness of my own, that I am led to suspect I have not made my meaning clear, and I therefore ask the privilege of restatement.

As I conceive the matter, the horizontal velocity of the bird with reference to the earth has no importance, and should be ignored. The earth enters the problem only by means of its attraction. Except for the gravitational pull, we need not consider the bird in relation to anything except the air. If a cloud intervened between the bird and the earth, so that he could not see the ground, he would not know in which direction the air surrounding him was passing over the earth; but the possibility of his soaring would not be affected by that ignorance. Provided the air in which the bird floats is not disturbed thereby, his motions would not be affected by the sudden reversal of the direction of rotation of the earth, although such a reversal would enormously change the relative velocity of bird and earth.

In my analysis of the subject I spoke of winds, that is, currents of air moving horizontally with reference to the earth, because such language afforded me a simple means of expression, and for that reason only. In so doing I took a special case as illustrative of the general case. As this seems to have been misunderstood by some of your correspondents, I will repeat the analysis in more general language.

Let the line AB represent in section a horizontal plane within the atmosphere. Conceive the body of air above this plane and the body of air below it to have different motions, such that their differential motion has the direction indicated by the arrows; that is

to say, the upper body referred to the lower moves from B to A , or the lower body referred to the upper moves from A to B . The movement of the two bodies collectively may be in any horizontal direction. They may both move toward A , the upper moving the swifter. They may both move toward B , the upper moving the slower. Either may be still and the other move past it, or they may move in directions approximately normal to the paper. My only postulates are, that their motions have no vertical component, and that their differential motion, z , has the direction expressed by the arrows.

The oval curve represents the assumed orbit of the bird as presented to an eye nearly in its plane. The bird ascending on one side of this orbit through the point C has, just before reaching that point, a velocity V as referred to the lower body of air, in which it is then moving. Immediately after passing C , his velocity referred to the upper body of air, in which he is then immersed, is $V + z$. He moves faster in the upper air, because when he enters it his direction is opposed to the direction of the differential motion of the upper air referred to the lower. His absolute motion both before and after passing the plane of separation is the same; but his relative velocity, that is, his velocity referred to the air through which he is passing, has been increased by the quantity z . Continuing on his circling orbit, he first ascends and then descends, reaching the plane of separation at the point D . While he ascends, gravity retards his motion; while he descends, his motion is accelerated by gravity to the same extent; so that he returns to the plane at D with the same velocity ($V + z$) with which he left it at C . He now passes from the upper body of air to the lower body in such direction that he again increases his relative velocity. As soon as he has passed D , his velocity referred to the lower air is $V + 2z$. Continuing to C , he first descends and then ascends, his velocity being first accelerated by gravitation, and then retarded by the same amount; so that he reaches C with the velocity $V + 2z$, in place of the previous velocity V , having gained the velocity $2z$ by passing in suitable directions to and fro between the differentially moving bodies of air.

The various qualifications of this theorem, and its relation to the problem of soaring, need not be repeated here. All that is now attempted is to show that the essential parts of the analysis are absolutely independent of the direction and velocity of air movement as referred to the ground.

It appears to me that Mr. Pickering and Professor MacGregor, by referring the motions of the bird partly to the ground and partly to the air, engender confusion, and are led to assume untenable positions. Mr. Pickering (xiii. p. 31) says that a piece of paper floating on the air is carried along horizontally with the velocity of the wind, but that a soaring bird does not drift so fast. Then, to account for the floatation of the bird, he appeals to the "force exerted on him by the wind, owing to the fact that he does not move along as fast as the surrounding air." Thus he assumes a force tending to prevent the bird from drifting horizontally with reference to the earth; and this assumption reduces the problem to practical identity with the problem of the ascent of a boy's kite. In point of fact, the assumed force does not exist: the only re-action between the bird and the earth is through gravity, and the direction of gravitation is vertical. If it be true that the soaring bird drifts less rapidly than the piece of paper, the explanation lies in something that the bird does; and that thing, whatever it is, costs energy. Appealing to the bird's net movement against the wind as a source of energy merely shifts the point of difficulty, for his net movement against the wind must then be explained.

Professor MacGregor says, "Let us suppose, now, that a bird is at any instant moving horizontally, in the same direction as the wind, and with a small velocity relative to the earth. . . . As his speed increases, the velocity of the wind relative to him diminishes" (xiii. p. 152). Now, if the velocities of bird and wind relative to the earth are so related that increase of the bird's speed diminishes the velocity of the wind relative to him, then it must be that the wind is moving faster than the bird, or is overtaking him. The context shows that Professor MacGregor conceives the bird to face in the direction toward which the wind blows, and it follows that with reference to the air the bird is moving tail first. I am confident that no ornithologist will admit the possibility of such flight; and its implicit postulation could hardly have occurred had the problem been stated wholly in terms of bird and air instead of being stated partly in terms of bird and ground. A little further on he says, "Let us suppose that in wheeling he maintains his velocity relative to the earth as well as his elevation. Then [after wheeling], starting upwards with a considerable velocity, he will clearly be able to rise through a certain height before his velocity has been reduced to its initial value." The assumption that the bird in wheeling maintains his velocity relative to the earth

appears to me absolutely groundless. The only velocity that can possibly remain constant, or approximately constant, during wheeling, is the velocity with reference to the supporting medium; and as that velocity is, according to his previous assumption, not only small, but negative, there is no energy available to enable the bird to rise. Indeed, the bird, in passing from a negative velocity relative to the air, to a positive velocity relative to the air, must pass through the phase of no velocity relative to the air, in which he is practically helpless, being compelled to fall vertically in order to acquire sufficient speed to steer. Like Mr. Pickering, Professor MacGregor treats the subject as though the earth influenced the motions of a bird on the wing by some other means than gravitational attraction. He apparently fails to perceive, that, if the body of air in which the bird moves has no internal motion, its relation to his flight is precisely that of a calm.

Let me illustrate. A steamer propelled with uniform force on a calm ocean has its rudder turned constantly, and by the same amount, to the right, and consequently describes a circle. This circle is described *on the ocean*: it expresses a relation between the moving body and that by which it is supported. It has no reference to the bottom of the ocean. It makes no difference whether that part of the ocean is at rest or is part of a swift current. The relation of the boat to the water is not affected by the relative motion of water and bottom. Or consider a skater. Having acquired momentum, he is able to describe circles without propulsive effort until the stored-up energy is consumed by friction and by the resistance of the air. The ice on which he circles may be frozen to the shores of a pond, or it may float with uniform speed on a rapid river; but his relation to the ice is the same in either case, and his circles have the same pattern as *engraved on the ice*. The case of the soaring bird is closely analogous. His horizontal motions are related only to the air in which he moves, and by which he is supported, and they are not affected by the uniform horizontal motion of that air with reference to the ground.

A slight correction, and I have done. I assume, as Professor MacGregor says, that after wheeling, the bird's velocity relative to the medium in which he turns will be the same as before (discounting friction); but I do not admit the implication "that during the turn his velocity relative to the earth will change by an amount equal to twice the velocity, relative to the earth, of the medium in which the turn is made." His velocity relative to the earth will change by an amount equal to twice his velocity relative to the medium.

G. K. GILBERT.

Washington, D.C., Feb. 25.

In two communications published in the last number of *Science* (p. 151) under the above title, Professor Pickering and Professor MacGregor have developed with considerable ingenuity a theory of the possibility of a bird soaring in a uniform horizontal wind; but it is certainly true that a bird cannot soar — that is, permanently sustain or elevate itself without expending energy — in such a wind, and it has therefore seemed to me to be important, in the interests of clear thinking, to show on dynamical grounds why soaring is impossible in this case.

Evidently the velocity of the wind relative to the earth has nothing to do with the question, as it is the relative movement of wind and bird that causes the re-actions between them, and therefore can alone come into consideration. Let the air, therefore, be supposed to be at rest relative to the earth, and it becomes at once obvious that the bird cannot soar: for, suppose the bird to have any imaginable initial velocity, and to wheel in the most artful manner, it is still a mass falling under the influence of gravity, and only resisted more or less by the fluid friction of the medium in which it is placed. This fluid friction of the air against its wings can only delay its fall, but can never prevent it, just as it delays the fall of a feather.

A theory of soaring must explain how energy is given to the bird by the wind; but it is clear, that, instead of the bird receiving energy, it is expending either its kinetic energy, as when in one of its whirls it sweeps upwards, or potential energy when it sweeps downwards. But the temporary increase of potential energy in a rise can never equal the corresponding loss of kinetic energy, because energy is being continually expended in frictional heating. There is thus a steady expenditure of energy, and none received

from the medium, and the bird is therefore bound to come to the ground. The only effect of the medium is to resist the motion, in whatever direction it may take place, whether up or down.

As soon as it is clearly seen that the only thing we are concerned with is the relative motion of air and bird, and that the air may be at rest relative to the earth without affecting the question in the slightest, the futility of any attempts to explain soaring in a uniform horizontal wind is apparent.

If any one wishes to discover the particular fallacies in the theories above mentioned, let him attempt to follow out the reasoning as given in the communications referred to; assuming, however, that there is no wind, that the air is at rest relative to the earth; remembering that the mere fact of the earth's moving relative to the wind has no connection with the relation between the bird and the air.

The theory that soaring can be kept up by taking advantage of differentially moving layers of air is not open to the above criticism, and may be the true explanation: it is certainly not unreasonable on its face.

ARTHUR L. KIMBALL.

Johns Hopkins University, Baltimore, Feb. 25.

To keep Water-Mounts Moist.

In biological work with the microscope it is frequently desirable to preserve water-mounts for several days, that growth, development, etc., may be observed from time to time. Water lost by evaporation can be very successfully replaced to the glass slips from a beaker beneath by means of capillary tubes. To make these, hard-glass tubing of about three millimetres bore is softened in a Bunsen flame, and then drawn out to a diameter of from two-tenths to three-tenths of a millimetre. This is then divided up into lengths of five centimetres, and each piece bent at an angle of about 80° one centimetre from an end by holding it over a very small flame for an instant, when, of its own weight, the end falls to the proper angle. One tube is sufficient for a slip, and is applied by first touching the longer limb in water, when instantly the liquid will rise and fill the tube, which may now be suspended by the shorter portion from the glass slip, allowing one end to just touch the edge of the cover-glass, and the other to dip beneath the surface of the water in the beaker. A thin film of water will run along the shorter limb, and hold it securely in place. The whole is then covered with a suitable bell-jar. In this way mountings in water or nourishing solutions may be kept an indefinite time, and are always ready for examination without disturbing them in the least. Should it be desired to supply more fresh water or nourishing solution to the mount than would ordinarily arise, a bit of filter-paper applied to the side of the cover-glass opposite the capillary tube will accomplish this.

Color-Blindness a Product of Civilization.

THE following is a summary of a paper read before the Kansas Academy of Science at Leavenworth, Nov. 1, 1888:—

The fact that blindness to certain colors exists among civilized people is well established; also the percentage of cases to be found among males has been determined with considerable probability for the races of Europe and America. There has been much diversity in methods of testing, and the results of many reported determinations might well be called into question. Still it is probably not far from the truth that about four out of every hundred males are more or less deficient in color-sense. Of females there have been reported (B. J. JEFFRIES, M.D., *Color-Blindness*, p. 74) as examined in Europe and America 39,828; and of these, only 60 were color-blind, or 2 per cent. Of both males and females, 156,732 have been tested; and of these, 6,721, or 4.27 per cent, are color-blind. These statistical facts have naturally excited interest and discussion. If so large a number as four out of every hundred are unable to distinguish colors, there arises, of course, a practical question important to the railroads, marine, etc.

The gravity of this fact is already recognized more or less in all countries by the test examinations for color-blindness among employees. But there is in these statistics also much of interest to scientists.

Most cases of color-blindness are found to be congenital, and are incurable. Many have been produced by disease, some by violent concussions in accidents, and some by excessive use of tobacco and alcohol. Temporary blindness to violet may be induced by santonine. From these facts several interesting questions have suggested themselves to us. If color-blindness follows the law of heredity, is it on the increase, or decrease? Further, is it a product of civilization? The first of these queries can be answered only by statistical data extending over long periods of time. The second naturally suggests a comparison, first, of the color-sense of civilized nations among themselves; and, second, of civilized with uncivilized peoples. Of tests in native tribes, we can find but two recorded,—those of Dr. Favre on some tribes in Algiers, and those of a Dr. Fox on 150 American Indians, but where we do not know.

First, for the comparison of civilized tribes among themselves, we have calculated the following percentages from tables reported by Dr. Jeffries:—

	No. Examined.	Per Cent Color-blind.
Austria.....	5250	3.79
Denmark.....	5840	3.74
Belgium.....	8106	4.13
Holland.....	2300	1.43
Finland.....	1200	5.00
Norway.....	205	4.88
Sweden.....	32504	3.73
Switzerland.....	3024	5.36
Germany.....	6344	4.12
Russia.....	12830	3.30
Italy.....	2065	2.32
England.....	16431	3.75
United States.....	44844	3.64
Average per cent.....		3.76

No great reliance can be placed upon these results. The numbers examined are too small, the methods of testing not uniform, not equally reliable. However, the probabilities of error are about equally distributed; so that the conclusion is fairly well established, even without great accuracy of data, that among civilized nations color-blindness is at present almost equally common.

Second, among uncivilized people, Dr. Favre's results from Algiers, already alluded to, show 414 examined, and only 2.6 per cent color-blind. Dr. Fox reports 161 young Indians tested, and only 1.81 per cent color-blind. These percentages, so low compared with those for civilized people, suggested to us that color-blindness may be a product of civilization, and have led to our tests here reported. At the Haskell Institute at Lawrence, Kan., are several hundred Indians, representing many tribes. These we have recently examined by Holmgren's method with Berlin wosteds. Out of 418 tested,—285 males and 133 females,—only three cases of color-blindness exist, or only .7 of one per cent. These three are full blooded Indians of the Pottawattamie, Pawnee, and Crow tribes. Of these, two have defective color-sense for red, and one for green.

The Indians of the school are about equally divided as full-bloods and half-breeds. It seemed to us that the half-breeds showed more instances of blunted color-sense than the full-bloods. This was evidenced in more frequent and prolonged hesitation among them in comparing the colors than among the full-bloods. If this was confirmed by more extended examinations, it would, in conjunction with the low percentages obtained as above, be an argument in the theory proposed by us that defective color-vision is in some way the product of civilization.

The use of tobacco suggests itself as a possible cause. This would explain also the low percentage among females. It leads also to the thought of increase of color-blindness in males in future

generations. But the data are at present too meagre to more than suggest this explanation.

It is certainly not accidental that nearly every case of color-blindness is for red, few for green, and seldom one for violet. Why are the defects thus limited, at present at least, to the longer wavelengths of light?

The Young-Helmholtz theory of color-perception will locate the affection in that layer of the retina corresponding to the first of the three primary sensations of color. But why this special layer, with few exceptions, is the only one affected, has at present no explanation.

The law of heredity indicates increasing sensitiveness in those nerves which are subjected to special use through many generations. It seems reasonable to look for an explanation of the more perfect color-sense in females to this fact; but among males there will probably be an increase, in future generations, of the number of cases of defective color-sense.

L. I. BLAKE.
W. S. FRANKLIN.

Lawrence, Kan., Feb. 19.

Note on the Wind-Pressure Constant.

THERE is a very old formula in use among English and American engineers and meteorologists for obtaining the force of the wind from its velocity. The product of the square of the wind's velocity in miles per hour into the factor .005 is taken as the pressure in pounds upon each square foot. It is used alike at sea-level and on the tops of high mountains, and in the extreme temperatures of winter and of summer, notwithstanding the pressure must vary as the density of the air. This is the value of the factor determined by Rouse from experiment about one hundred and fifty years ago, and of all the crude experiments which have been made from that time to this, and before. It seems to be an extreme value. Of a number of the older determinations of this factor, it is stated, in Gehler's "Physicalische Wörterbuch," that this is the worst, while those of Hutton and Woltman are perhaps not much in error. It is astonishing to see, therefore, with what tenacity engineers and meteorologists still hold on to this factor. It has been maintained by the writer for several years that this factor is much too large,—first in *Van Nostrand's Journal*, 1881; then in "Recent Advances in Meteorology;" and in the *American Meteorological Journal*, 1887. It was shown that the theoretical value of the factor, not considering friction, is .0027; and it was thought that this could not possibly be increased to .005 by the friction of the air. And it was shown that this view of the matter is confirmed by Loomis's results obtained from the discussion of experiments made by the request of Newton in St. Paul's Cathedral, London, upon the velocity of the falling of hollow glass globes and of bladders, and of Hutton's experiments with a whirling-machine. From all these researches, and also the somewhat recent experiments of Hazen with a whirling-machine, it was concluded that the theoretical constant above could not be increased by friction more than one-tenth, or, at most, one-eighth part. But the old factor has been in use so long, that conservatives think it must be correct, and so are unwilling to give it up.

A further confirmation of the erroneousness of the factor is now found in the last number of the *Quarterly Journal of the Royal Meteorological Society*, which contains a report from the wind-force committee appointed by that society. The committee, as yet, have made only a few preliminary experiments in this part of their work; but the average value of the factor from these is .003, which is about one-tenth part greater than the theoretical value given above. This will, no doubt, be changed a little in their final report, after more experiments shall have been made; but as it agrees nearly with the factor obtained by Hazen, and with what is to be inferred from other experiments, it is not probable that the final result will vary much from this.

This is a factor in which engineers are especially interested, and its value ought to have been accurately determined by them long ago; but, as the Royal Meteorological Society has now taken it in hand, it is to be hoped that its committee will do the work thoroughly, as they apparently intend to, and determine the value of this factor accurately, not only for plates of different sizes and shapes, but also for different temperatures and barometric pressures.

Mental Evolution of Man:

THE ORIGIN OF HUMAN FACULTY. BY GEORGE JOHN ROMANES, F.R.S., author of "Mental Evolution in Animals," etc. One vol., 8vo, cloth. Price, \$3.00.

This work, which follows "Mental Evolution in Animals," with the same author, considers the probable mode of genesis of the human mind from the mind of lower animals, and attempts to show that there is no distinction of kind between man and brute. It is likely to provoke no little discussion in the religious and literary as well as the scientific world.

"The vast array of facts, and the sober and solid method of argument employed by Mr. Romanes, will provide, we think, a great gift to knowledge."—Saturday Review.

The Folk-lore of Plants.

By T. F. THISELTON DYER, M.A. 12mo. cloth. Price, \$1.50.

"The Folk-lore of Plants" traces the superstitions and fancies connected with plants in fairy-lore, in witchcraft and demonology, in religion, in charms in medicine, in plant language, etc. The author is an eminent English botanist, and superintendent of the gardens at Kew.

STAR ATLAS.

Containing Maps of all the Stars from 1 to 6.5 magnitude between the North Pole and 34° South Declination, and of all Nebulae and Star-Clusters in the same region which are visible in telescopes of moderate power. With Explanatory Text, by Dr. HERMANN J. KLEIN. Translated and adapted for English Readers, by EDMUND McCLEURE, M.A., M.R.I.A. 18 Charts and 84 pages of illustrative letter-press. Imperial 4to, cloth. \$2.25 net. If by mail, 20 cents must be added for postage.

"I have been looking for just such an Atlas for more than thirty years. The absence of those historical charts which adorn most all star maps and every celestial globe is certainly a great loss. The astronomer wants the outlines only of the constellations on his star-maps. The insertion of Nebulae and star-clusters visible in small telescopes only, is a boon to the astronomer who does much work (or any) in searching for Comets; and as this work is mostly done with small telescopes the ob- ject will have little value."—H. P. TUTTLE, M.A., formerly of the Cambridge (Mass.) Observatory.

"I have carefully examined the Star Atlas... and consider it in every respect a first class work... The maps are clear, distinct and remarkably accurate, the boundaries of the constellations agree exactly with the very best authorities; the names are marked distinctly. The Nebulae and star-clusters are all marked and carefully named down to such a magnitude as could be seen with an ordinary two or three-inch telescope, and their positions are remarkably accurate. The descriptions of astronomical phenomena are given by the best authorities and with the heavens; they are accurate and just as exhaustive as possible for the space. The pictures of some of the most important phenomena are derived from the best sources, some of them excellent copies, and others quite accurate representations of the heavens. The whole work was written by an astronomer of acknowledged reputation, which itself is a sufficient recommendation. The book is very handy and it surprises me how much is contained in such a small compass; it is practical, for no stars or other objects are put down below a certain limit, and it is practically exhaustive up to that limit. There are three classes of people that it may benefit. 1. Astronomers who are particularly engaged in comet hunting; on account of the Nebulae being marked as they are. 2. Amateurs with two or three inch telescopes who want to get a general view of the sidereal heavens. 3. Students for I think a copy of this Atlas would be extremely useful as a hand-book where sidereal astronomy is taught in any manner. It gives me great pleasure to state that I do not know of any book of its kind that contains so much accurate knowledge in so small a compass."—EDGAR KRISBY, Professor of Mathematics, U. S. Navy. U. S. Naval Observatory, Washington, D. C.

Insurance.

DEATH IS DANGEROUS.

We call attention to the new form of Accident (indemnity) Insurance policies, which are written by the Merchant's Casualty Insurance Association, 21 Park Row, New York City, John S. Purdy, Secretary. These policies cover weekly allowances of from \$10 to \$25, according to occupation, at a cost of only \$6 a year exclusive of the cost to join, which is \$5 payable once only. The public, as a rule, carry life insurance, and the ordinary accident policies issued by companies, paying a sum in case of death, is not so desirable as one of these indemnity policies in case of accidents, which are so plentiful in this fast age with its railroad horrors, fast driving, electric wires and other countless forms of danger to which the public is constantly exposed. The fact of the Association having no unpaid claims, and its having just passed an examination by the Insurance Department of New York State, shows that the management is liberal with its policy-holders and conservative in its action. The Association also desires to secure energetic Agents in every village and town, to whom territory and favorable terms will be given.

TO EMPLOYERS.

Having purchased the fixtures, good will, &c., of the NEW YORK EMPLOYMENT BUREAU, at No. 681 BROADWAY, in this city, we request the patronage of the public in the future. We desire to fill a long-felt want for an employment bureau, where only the best grade of male help is dealt in, and it is our aim to send ONLY such help as is ordered in every instance, and our patrons can rely on us to send strictly first-class help, the references of whom we personally investigate before sending to any one. We simply request a trial, and are convinced that we will give satisfaction in every case. We have on hand help in every branch, which we can send upon receipt of telegram or letter, AND FOR WHICH WE MAKE NO CHARGE TO AN EMPLOYER.

SOME NEW ELECTRIC RAILWAYS.

We present in this issue a view taken from a photograph, last summer, of one of the electric cars on the Naumkeag Street Railway of Salem, Mass., of which Mr. Charles F. Odell is president. This electric road was equipped during the past year by the Sprague Electric Railway and Motor Company of New York, for the summer traffic between the city of Salem and a watering-place about a mile or two away, known as the Willows.

The cars ran very successfully all last summer while in use, carrying large numbers of passengers, and giving perfect satisfac-

tion to the president and directors of the road, who, it is said, intend adding more electric cars in the spring, and extending the line as far as Beverly.

The illustration which we give presents a good idea of the large number of passengers which these cars often carry on pleasant days during the summer. In spite of the heavy load, these cars move with quickness and despatch, and mount the steep grades on the line at the rate of eight or ten miles an hour. These grades, before the introduction of electric power on the road, have often compelled horses to succumb in drawing the heavily loaded cars.

The regular Sprague overhead system in use upon the road here

includes the small No. 6 wire as a working conductor, which is the only wire suspended over the centre of the track; the main current being carried at the side upon a heavy copper conductor, which is connected at intervals of every one or two hundred feet to the working conductor.

One of the most important electric railways in the country is that in operation at Cleveland, O., also on the Sprague system. We present a view on the road, showing one of the Sprague cars drawing another on Euclid Avenue. The road has been in operation now for about a month, and has carried a large number of passengers, who are delighted with the new motive power, and the

SPRAGUE ELECTRIC RAILWAY AT SALEM, MASS.

quickness with which the cars can be started and stopped, their speed, and the ease with which they mount the grades and round the curves. The lighting of the cars by electricity is another great advantage.

The equipment of this road is similar to that of the Sprague Electric Road in Boston, Mass. The poles used are of iron throughout the entire length of the line, and the overhead work is unobtrusive, making the whole line-work unobjectionable. The power-station for generating the current is one of the most complete of its kind in the country. It is fitted with Edison dynamos, Armington & Sims engines, and every thing is so arranged that its

capacity can be easily quadrupled without changing the line of machinery.

Since the road has been in operation, it has been visited by delegations from all sections of the country, of railroad men, who have inspected the operation of the road with the view of introducing the Sprague system upon their own lines. The East Cleveland Railway Company have afforded them every opportunity for inspection, and the result has been that a large number of contracts since the opening of the road have been awarded to the Sprague Company.

In a recent snow-storm which occurred in the city of Cleveland, the tracks were all covered to a depth of from six to eight inches; and the horse-railways in that city were delayed in their trips, and only ran intermittently. The electric road, on the other hand, made regular trips, ploughing its own way through the drifts, and successfully demonstrating the advantages of electrical

On account of the perfect regularity of speed which is the characteristic of these motors, on account of their differential winding, they are peculiarly adapted to the operation of printing-presses. There are also several machine-shops, carpenter-shops, and elevators which are using the Sprague motors.

HEALTH MATTERS.

Climate of Colorado.

DR. WALTER A. JAYNE presented an exceedingly interesting paper, on "The Climate of Colorado and its Effects," to the American Climatological Association at its recent meeting. In his paper he discusses the air of Colorado both as to atmospheric pressure and dryness. The annual rainfall is between fifteen and sixteen inches, — a small amount as compared with the United States in

SPRAGUE ELECTRIC RAILWAY AT CLEVELAND, O.

over animal power. The Sprague Company are now equipping snow-ploughs, to be operated by powerful electric motors, for this road; so that no snow, however deep, will be able to stop the running of the cars. It is estimated that these electric ploughs will clear the tracks quicker than an ordinary plough drawn by a dozen horses.

Among the cities which are coming into prominence in the Southern States, there is none probably in which the application of electricity for industrial purposes has received greater attention, and been more extensively applied, than in Asheville, N.C. We gave a description, in a recent issue, of the successful opening of the electric railway which connects the city of Asheville with the railroad-depot, distant about a couple of miles, which has been running successfully.

Although possessing a successful railway, the attention of the Asheville citizens in regard to electric power has not been devoted exclusively to railway-work; but there are a number of stationary motors in the city which are giving satisfaction. Both the Asheville *Citizen* and *Country Homes* are printed by electric power.

general. The winds are at times disagreeable and annoying by reason of the dust, but no injurious effects result from them except physical discomfort. In concluding his paper, he says that there are one or two very simple rules which all consumptives coming to high altitudes should understand and observe, since, because of the unusual characteristics of the climate, they are so important that neglect of them will retard recovery, and in advanced cases may destroy the slight chance still remaining to the invalid of receiving benefit from the change, and lead to a fatal result.

1. The approach to elevated regions should be gradual and by easy stages, not, in these days of Pullman coaches, to spare fatigue, but in advanced cases with limited lung space, and in those with fever and considerable activity of the disease, to avoid over-taxing the capacity of the lung to adapt itself to the rarefied atmosphere. For the same reason the invalid should, for a time after arrival, either take very moderate exercise or none at all.

2. The residence should be continuous and prolonged.

He is confident, that, were the first of these rules more generally followed, we should hear far less of the ill effects of high altitudes,

and be able to note a larger percentage of advanced cases as improved; and if the second was faithfully observed, there would be more cures and fewer relapses.

Overcoats.

The custom in this country is so prevalent of wearing heavy overcoats, whether one is outdoors or seated in overheated cars, that the remarks of the *London Lancet* on this useful garment will probably find interested readers. The teaching of modern science and of ancient custom goes to show that heat-production within the body has much to do with the tissue changes concerned in muscular activity and with healthy digestion. It is conserved by warm and moderate, wasted in evaporation by excessive, clothing. Finally, by a simple nervous re-action, it is increased after the contact of external cold.

It follows from these observations, that, if we be so clad with comfortable underclothing that surface perspiration is not formed in excess, and is rapidly removed, one great cause of chill—sudden evaporation—is done away with. Outer cold, then, provided it is not too severe, only touches, as it were, the spring of the heat-making metabolism, and, exciting an elastic rebound in the chain of vaso-motor fibres, awakens that oxidative action by which every tissue is made to yield its share of heat to the body. This bracing influence is lost wholly or partly to those who are too heavily clothed, and in its place we may have a dangerous excess of surface heat. It is for this reason that the *Lancet* has before protested, as it now does, against the indiscriminate use of the thick and heavy overcoat; and it thinks that men in fairly robust condition, especially if young, should be clad warmly next the skin, and wear either a light top coat or none at all.

There can be no doubt that the habitual use of great-coats is indirectly accountable for the chills which they are intended to prevent. Were the overcoat worn continuously, it might attain its object. Its intermittent use, even when ample underclothing is worn, affords no solid guaranty of safety, but rather the reverse. The man of sedentary habits has especial need to remember this. He emerges daily from a warm breakfast-room clothed in his ordinary winter garments, with probably woollen underwear, and over all the heavy ulster or top coat. After a short walk he finds that the sense of warmth he began with is more than maintained. He arrives at his office or place of business, and off goes the overcoat, though the air of the newly opened room is as cold as that without, and draughty in addition. During the day perhaps he travels to and from adjacent business-houses, wearing only his house clothing. The overcoat is laid aside till closing time reminds him of the journey home. The frequent result is, that somehow, between the hours of his departure and return, he is chilled. No doubt he would run as great a risk if, lightly clad, he were to face the rigor of a winter day. In this case, however, exercise and habit might do much to develop the power of endurance, and there would, at all events, be less danger of sudden cold acting upon a freely perspiring surface. Woollen underclothing represents a state of healthy comfort intermediate between these extremes, and more resistant to chill than either.

In commending its use, however, the *Lancet* does not assert that the influence of age and constitution is to be overlooked. Youth can oppose a power of resistance to depressing agencies which does not reside in the worn-out nerve-centres of a ripper age. Similarly, that elastic re-action which characterizes the nervous and sanguine types is not to be looked for in the lax tissues of the lymphatic. The weaker physique naturally calls for fuller protection than the stronger; and any rule requiring the disuse of the overcoat should allow of reasonable exceptions in favor of the old and constitutionally feeble. Unusual severity of weather, especially if associated with night air and the loss of sleep which this implies, is another condition which might well constitute an exception. In such a case we are compelled to add some form of overcoat to the ordinary amount of clothing. Some parts of the body—for example, the chest, throat, and feet—are certainly more susceptible to cold than others. As a useful safeguard, cold or tepid bathing of such parts is in merited favor. The custom so common with many persons, especially women, of walking out in thin-soled boots, often plays an important part in catching cold.

The progress of time and of rational thought may be expected to bring in a more comfortable arrangement by clothing the foot in woollen hosiery and a stouter boot.

SWINE OR MAN.—It is said that more money has been spent by the United States Government in the investigation of the diseases which affect swine than of those which affect the human species.

AIR AND WATER ANALYSES.—Modern investigators are not satisfied with chemical analyses of drinking-water and air as tests of their purity, but demand a biological test as well. Bujwid has recently been examining the air and water of the city of Warsaw by the most modern methods. He states that pathogenic micro-organisms are ordinarily found in the air: it therefore follows that disinfection of hospitals and operating-rooms is of no practical value or significance. Certain micro-organisms which may be found in the air Bujwid failed to find during investigations over a period of three years. Of those found in the air non-pathogenic, but one not yet known gives rise to suppurations in mice and rabbits; the rest are innocuous. The number of bacteria in the air is subject to great variations, and depends largely upon the winds and conditions of habitation. After a rain or snow the number is smaller. Basement rooms and abodes contain the largest numbers. On an average, one hundred thousand times more bacteria are found in water than in air. Good water should not contain more than three hundred rod bacteria to the cubic centimetre (0.06 of a cubic inch). Different results were obtained from the examinations of water from various springs and running streams. Above the city the water contained about three hundred bacteria, in the midst of the town over fifty thousand, to the cubic centimetre. Bujwid found no pathogenic micro-organisms whatever. After filtering this same water (sand-filters have recently been introduced into Warsaw), the proportion of bacteria diminished from twenty to sixty. Spring water contains a still larger number of micro-organisms. In the discussion which followed a presentation of these views by Bujwid, Barzyci stated that in a village near the city of Rzeszow, having no spring, a peasant living by the creek was affected with typhoid. His linen was washed in the stream. Shortly many of the inhabitants who obtained their drinking-water from the creek, and who lived below the house in question, likewise sickened with typhoid: all living above escaped.

BALDNESS.—As our readers are already aware from the discussions which have already appeared in *Science*, various theories have been proposed to account for the baldness which prevails to such an extent in civilized countries. A Swiss writer attributes it to a microscopic fungus, which, however, he has not as yet been able to describe or indeed to discover. He thinks that barbers should be compelled to disinfect their combs and brushes.

BOSTON MILK-SUPPLY.—In no city of the United States is the food-supply more carefully watched than in Boston. The inspector of milk of that city has just made his thirtieth annual report, which covers the work performed by him during the year 1888. From this report it appears that 915,867 more gallons of milk were sold in 1888 than in 1887, and, notwithstanding this increase, the quality was much better. In 1883, 60 per cent of the milk examined was found to be below the standard fixed by law. In 1884, only 40 per cent was below; in 1885, 30 per cent; in 1886, 18 per cent; in 1887, 12 per cent; and in 1888, but 8 per cent. The inspector justly claims this great improvement as the result of the labors of his department.

THE MICROBE OF MALARIA.—The evidence is accumulating that the microbe of malaria which was described by Laveran is the cause of intermittent fever. At a recent meeting of the French Academy of Sciences, Professor Bouchard expressed the opinion that Laveran's claim had been substantiated.

BOOKS FROM CIRCULATING LIBRARIES.—Subscribers of public libraries have of late been warned against the danger of contracting contagious diseases from books which have been in houses where these diseases existed at the time. The health authorities of Dresden have been examining the dust which had accumulated on unused volumes, with reference to the discovery of

micro-organisms, and especially the bacillus of tuberculosis. They report that they have found nothing of a harmful character, and have arrived at the conclusion that the danger of spreading infection by means of circulating libraries is very slight. They recommend, however, that books should be well dusted before being read, and that the fingers should not be wet in the mouth in order to turn the leaves. If the experiment is correctly reported, the authorities of Dresden are not justified in deducing any such inferences. The material which may accumulate in the form of dust on "unused books," and that which may collect on books in infected rooms, are of a totally different character. To determine the danger from the use of these latter books, another series of experiments must be made, and, in the present state of our knowledge as to the germs of infectious diseases, not much could be expected even from such experiments. The germs of measles, scarlet-fever, and small-pox, which diseases are known to be propagated by articles of wearing-apparel which have been exposed in infected rooms, have never been recognized, and the search for them in the dust which has collected on books would doubtless be as futile as it has been elsewhere; but there is no *a priori* reason why such books might not be carriers of contagion equally with clothing and furniture. The advice given to dust books well before reading them, in order to avoid danger, is, if the Dresden authorities are correct in saying that such dust is harmless, entirely unnecessary, while, if the dust should be infected, it would be the best possible way to spread the infection. Books which have been in an infected room, especially if they have been opened, should be destroyed. It is practically impossible to disinfect them.

THE LOCO-WEED.—Readers of *Science* have from time to time written us regarding the "loco-weed" and its poisonous properties, and we have recorded every thing which could be learned about its effects on animals and men. In Vol. IX. p. 32, we referred to a curious affection which exists among horses in north-western Texas, known as "grass-staggers," which is caused by eating the "loco-weed," which gives rise to the saying that the horses are "locoed." The Indians believe that an insect is the cause of the disease, but competent investigators have failed to find any insect life upon the plant. In Idaho the same disease is found, and is treated by amputation of the tails of the affected animals (*Science*, ix. p. 306). Francis H. Snow of Lawrence, Kan. (*Science*, ix. p. 92), refers to observations which tend to support the idea that insects are connected with the causation of the disease. Professor Sayre of the University of Kansas was said to be making an exhaustive study of the "loco" problem. Dr. Mary Gage Day of Wichita, Kan., has recently made a number of experiments upon healthy cats to test the toxic qualities of the weed, and has communicated the results to the *New York Medical Journal*. The "loco-weed" is a popular name given to *Astragalus mollissimus* and *Oxytropis Lambertii*. In the experiments of Dr. Day, a decoction of the roots, leaves, and stems of plants gathered in September was used. The result of feeding the decoction to a kitten was to produce diarrhoea, vomiting, convulsions, paralysis, and, at the end of twenty days, death. After death, ulcers were found in the stomach and intestine. In another experiment with a more concentrated decoction, on a full-grown cat, the symptoms were much the same, the cat dying on the thirteenth day. Professor Vaughan of the University of Michigan made experiments on frogs and kittens, injecting the decoction under the skin, producing death. With reference to the character of the plants at different seasons of the year, Dr. Day is convinced, by numerous experiments on material gathered in different months, that the greatest amount of poison is present in the autumn and winter, after the seeds have ripened, and that the explanation of the ranchmen, that the "loco" disease is more prevalent in the autumn and winter because the animals eat more of the weed from the scarcity of other food, is only a partial explanation. The greater toxicity of the plants at that season she believes to be a very important element. From the facts and experiments detailed, the following conclusions are drawn: 1. There is some poison in "loco-weed" which may cause the illness, and, if sufficient quantity is taken, the death, of an animal. 2. This poison is contained in the decoction obtained from the plants, and, by systematically feeding it to healthy cats,

cases of "loco" disease may be produced. 3. From the large quantity of the plant or the decoction required to produce the disease, the poison must be weak, or, if strong, it must be in very small amount.

SCIENTIFIC NEWS IN WASHINGTON.

Effect of Permanent Moisture on Certain Forest-Trees.¹

In 1874, while engaged in the work of the Kentucky Geological Survey in the lowland district near the Mississippi, I had an opportunity of making some inquiries concerning the knees of the swamp cypress, which led me to the supposition that these peculiar processes from the roots served in some manner to aerate the sap. Their functional importance was indicated by the fact that whenever their summits were covered by water, as by the sinking of the ground on which they stood in the earthquake of 1811, or by the artificial elevation of the water during the summer season in mill-ponds, the trees to which they belonged inevitably died. On the other hand, the trees which grew upon high ground failed to develop any knee processes beyond slight tuberosities on the upper side of their main roots. The results of this and other inquiries were put in press about twelve years ago, but were first published in Vol. XVI. No. 1, of the "Memoirs of the Museum of Comparative Zoölogy at Harvard College," June, 1887. An incidental reference to the fact was made in the third volume of the reports of progress of the Kentucky Geological Survey (1877), p. 74.

Since that time I have incidentally observed certain other phenomena connected with the conditions of our forest-trees in swamps, which, so far as my knowledge goes, have not received adequate attention. I have hoped to find an opportunity to make a more careful inquiry into the subject, but this does not seem possible. I therefore venture to give the results of the very incomplete investigation in this letter.

As it seemed unlikely that the cypress should be the only tree to develop root processes intended to fit the plant for semi-aquatic life, I searched for similar excrescences on the roots of our other forest-trees which find their station in wet lands. Until within a few months, I have been unable to find any other species in which the processes were sufficiently developed to be classed in importance with the cypress knees. (A very little inquiry showed me that all trees which find a station in very wet lands have their large roots nearer the surface of the soil than in the upland districts, and several species exhibit a tendency to have their roots at certain, points actually on or above the soil.) Observations in the Mississippi swamps seem to show that our ordinary tupelo or sour gum (*Nyssa uniflora*, Walt.) exhibited rather more of this tendency than any other species, and I suspected that under favorable circumstances it might show a peculiar adaptation to its swampy surroundings. Observations in the Mississippi valley were difficult, for the reason that the pools beneath which the roots of the trees extend dry out during the summer droughts. Recently, however, in the Dismal Swamp district of Virginia and North Carolina, I found many areas occupied by the tupelo which did not become desiccated in the dry seasons. In all such positions, the tree, when of mature growth, has a peculiar feature in its roots which serves in an admirable way to accomplish the results attained by the cypress knees, though the method by which it is attained is peculiar. In place of forming a spur-like process upon the root, the root itself arches upward in such a manner that the upper part of the bow rises above the level of the water in the growing season. Where the depth of water is slight, the arch may be indistinctly developed. Where the water stands a foot or more in depth, the arch becomes very much elevated. I found specimens in which the roots assumed a horseshoe-like curve, rising to the altitude of three feet above the soil, the distance apart of the roots at their base not exceeding a foot. These roots commonly have a diameter of from three to six inches. The fact that they rise above the level of the water in the growing season is often attested by a considerable growth of annual plants which have become planted in the crevices of the bark.

These roots of the *Nyssa* do not appear to develop their arches until the tree attains a considerable size. I found no trace of them

¹ Preliminary notice of some results of the United States Geological Survey examination of swamp-lands, by N. S. Shaler.

in the cases where the plant was less than one foot in diameter at the ground, and they do not become a conspicuous feature until the tree is nearly adult; i. e., until it has attained a diameter of eighteen inches or more. At this stage of growth, if the crown be permanently wet, the knees become an extremely conspicuous feature, fifteen or twenty often being found grouped about a single stem at the distance of from five to twenty feet from the base of the bole. It thus appears tolerably certain that the need of having a portion of the roots above the water-level will be found in certain other trees. Thus far my note-books supply me, however, no certain indications of this fact. Indeed, it is only in the case of *Taxodium* and the tupelo that I have found the plants under circumstances which would show clearly their needs in this respect.

There is another feature concerning the growth of water-loving trees, or at least those which are tolerant of permanent moisture, that deserves attention. I have reference to the form of the bole or trunk as it is exhibited in the specimens of the Southern species, which occupy situations diversely affected by moisture. On very wet ground the trunk appears to be generally expanded at the crown, in a measure, which is not the case in specimens of the same species growing in dryer situations. Thus, in the cypress, we not infrequently find the bole at the crown, and for some feet above, having a diameter twice as great as it is at ten feet above the surface. Where, however, the tree grows on a dryer soil, the expansion at the base is much less considerable. The same appears to be the case in the tupelo, which often has a remarkable expansion of the trunk near the surface of the ground, where the plant occupies very wet situations. In a somewhat less degree, this feature appears to exist in all our trees, except the willows, which occupy sites characterized by diversity in the measure of wetness. I should state that this opinion rests entirely on eye-measurements. I have long intended to submit the impression to the criticism of a careful determination, but have not been enabled to do so. The impression has, however, been so often repeated to me in different regions, that I am inclined to believe there is little chance of error in the statement. I trust that some one who is well placed for such observations will subject the suggestion to a careful statistical inquiry.

If I be correct in the opinion that trees in very wet situations develop an enlarged bole near the surface of the ground more frequently than those which occupy dryer situations, we may perhaps account for the fact in the same way in which I am disposed to explain the occurrence of knees in *Taxodium* and of root-loops in the tupelo; viz., through a need of an aeration of the sap, which is denied in roots that are under water.

It appears to me from eye-observation, as yet uncorrected by measurements, that the buttresses which the water-loving trees form about the trunk are more considerable than they are in the same species on higher land. If this be really the case, it may perhaps be due to the same physiological need which has led to the formation of knees, and to the enlargement of the bole near the crown of the tree. I feel less confident as to this increase in the buttress prominences than I do concerning another observation which I have above set forth. I state the impression for the reason that it has very frequently been borne in upon me in my studies on the development of swamp-plants. At first I was disposed to attribute the peculiarity to the fact that the roots of swamp-trees do not usually extend far beneath the surface, and therefore the buttresses were enlarged in order to give greater stability to the trunk. This hypothesis was disproved by the fact that trees growing in such situations are very rarely uprooted by storms. I failed, indeed, to find a single case of such uprooting by the action of the wind in several thousand miles of journeys through the morasses in the eastern part of the United States. The only cases in which such overturning met my eye appeared in the swamps near the Mississippi, which, on the whole, exhibit buttress structures much less conspicuously than the trees of the Atlantic coast morasses.

There is another interesting series of facts connected with the effect of excessive water on our forest-trees which are tolerant of swamp conditions. These relate to the variations in the character of the bark, the mode of branching, etc., of the plants in situations diversely conditioned as regards the amount of moisture. In almost all our forest-trees, which range from dry to very wet stations,

there are noticeable diversities as regards the above-mentioned features, according to the station they occupy. Thus the ordinary chestnut oak varies in a very noticeable manner between dry ground and wet. The tree in very wet situations has a much smoother bark than it exhibits on high land, and I am told by the woodmen that this bark in trees which grow within the swamp is unfit for the purposes of tanning. The variety of tupelo known to the woodman of the Dismal Swamp as the "pawpaw gum," appears to owe its peculiarities to the fact that it normally grows in much wetter localities than the ordinary *Nyssa*. It differs from the parent species in that the bole is singularly enlarged near the crown, often having a diameter for some feet above the surface of the water two and one half times as great as it has at the height of ten feet above the ground. In this connection it may be noted that this variety of the tupelo is less disposed to develop the root-loops than the more common form, it appearing indeed as if the great extension of the bole near the crown made the development of these processes unnecessary.

The variation in the character of our forest-trees when exposed to swamp conditions affords an extremely interesting field for an important class of inquiries concerning the influence of environment, and the effect of natural selection, on the development of organic forms. In the Dismal Swamp, where the water-level during the growing season is subject to relatively little variation, a difference in altitude of six inches, or at most a foot, will greatly affect the character of the timber-trees and other plants. With each such variation in height, we perceive a noteworthy change in the character of the vegetation.

MENTAL SCIENCE.

Statistics of Visual Images.

THE American Society for Psychical Research has devoted considerable time to the study of unconscious mental habits, a field that abounds in suggestions applicable to the class of phenomena which such a society investigates, but is still more valuable as contributing to our knowledge of obscure mental traits. Thus Professor C. S. Minot has shown that we are by no means as likely to think of one number as of any other, when simply asked to think of a number, but that there exist certain definite and very general preferences for certain numbers above others. People have "number-habits," or unconscious tendencies to choose a certain few numbers (perhaps on account of greater familiarity, easy manipulation, peculiar association, brevity of utterance, or other causes) when an unlimited choice is offered them. In No. 4 of the "Proceedings of the American Society for Psychical Research," Professor Minot brings together extremely interesting material for a similar study with reference to the "diagram-habit." The committee on experimental psychology of this society sent out a large number of postal-cards bearing the printed request, "Please draw ten diagrams on this card, without receiving any suggestion from any other person, and add your name and address." Five hundred and one such cards have been collected, of which 310 were drawn by men, 169 by women, and 22 had no name.

The first point of interest in such a study is to observe how various the drawings of five hundred persons will be. We are not told how many different designs occurred; but the occurrences of 83 different designs have been tabulated, and their sum includes about half of all the drawings. But the real poverty of the intellect when it expresses itself naturally is made evident by the great preponderance of a very few simple diagrams. Thus circles were drawn 209 times; squares, 174 times; equilateral triangles, 160 times; crosses, 160 times; letters of the alphabet, 82 times; diamonds, 80 times; oblongs (horizontal), 78 times; inscribed circles, 78 times; stars, 77 times; faces (profile to the left), 61 times; houses, 56 times; rhombi, 56 times; scrawls, 53 times; other animals and heads, 48 times; flowers, 46 times; leaves, 45 times; hexagons, 42 times; cubes, 42 times; right-angled triangles, 42 times; figures of men, 32 times; and so on. The above are the twenty most frequent drawings, and, it will be seen, form an aggregate amounting to nearly one-third of all the drawings. On the average, each occurs 80 times. If we group to-

gether the designs belonging to the same natural class, we find, of circles, both plain and with inscribed figures, 287; of squares, both plain and with inscribed figures, 236; of triangles, equilateral and otherwise, 220; of four-sided figures, 245; the sum of which four classes is 988, or nearly one-fifth of all the drawings. In other words, if a person is about to draw the first ten designs that come to his mind, it is a pretty safe prediction that two of the ten will be either a circle, a square, a triangle, or a quadrilateral.

Tabulation upon another basis reveals the fact that 2,344 diagrams were drawn exclusively with straight lines, and 1,337 diagrams with less than six straight lines; that 681 diagrams were drawn exclusively with simple curved lines, and 603 diagrams with less than six such lines. One is more than three times as apt to draw a diagram composed of straight lines than one composed of curved lines. Among the non-geometrical designs, animals, plants, and manufactured objects include by far the most frequent drawings. Men are drawn 32 times; hands, 10 times; flowers, 46 times; leaves, 45 times; and trees follow with only 14 times; houses are drawn 56 times; and the next figure under this class is 15 for books.

Furthermore, without any express implication in the request, the respondents have taken it for granted that ten different designs were wanted, and very few repetitions of designs occur. If the number of persons drawing each kind of design be tabulated, it reinforces the conclusion suggested by the original tabulation as to the limitations of the mind when acting as it does in these tests. 40 per cent of the respondents have drawn circles; 34 per cent, squares; 31 per cent, equilateral triangles; 25 per cent, crosses; 16 per cent, diamonds, etc.; and there are very few designs drawn by only one person.

What this research especially impresses is the lack of individuality in our off-hand mental products. As Dr. Minot well puts it, "We too easily forget our similarity, and forget that it stretches over trifling habits as well as over the great and little modes of thought. We feel, and for the most part willingly acknowledge, the likeness of our natures, but our sentiments and ideas we are over-inclined to consider original. Such tests as the drawing of the diagrams thrust home the conviction that even in trifles we differ very little. The images and notions which pass across the consciousness of each individual are almost all common property: they are comparable to coins,—every one is a separate entity, but yet the stamp is the same. Our thoughts are in a large measure owned by the community: we are in mental matters all pure communists."

There are other questions upon which these results shed interesting light. The first is the order in which one is apt to draw, and by inference to think of, the several designs. One would suppose that the designs occurring most frequently would also be the ones first thought of. The results, however, do not reveal as close an agreement as one would expect. They show that an equilateral triangle is more apt to be found among the first diagrams than any other figure. Then come squares, then right-angled triangles, then circles, then faces not in profile, then faces with profile to the right, then diamonds, then oblongs, and so on. It is possible that the order of frequency of diagrams occurring the very first of the ten would be more in agreement with the order of general frequency. Another interesting comparison is between the designs furnished by the men and by the women. Remembering that we have nearly twice as many records of the former as of the latter, we find that men have more than their share of circles, both plain and inscribed, of rhombi, of scrawls, of men, and of right-angled triangles, while women are fonder of squares, equilateral triangles, letters, diamonds, stars, faces, flowers, and so on. "That gentlemen preponderate with hearts, and ladies with hands, perhaps may seem to many a natural consequence of our social conditions;" and other of the preferences seem to have a natural basis. That many of them must be regarded as accidental is doubtless to be admitted. The general law, however, is that there is much more repetition, and thus much less variety, among women than among men.

A few residual points should be noted. Some of these designs are undoubtedly to be traced to the existence of a "form" in the mind towards which a person may persistently tend. The "num-

ber forms" so vividly described by Mr. Francis Galton may serve as a type of such habits. When toying with a pencil in one's hand, many persons will find themselves drawing over and over again a simple figure. This accounts for some of the very peculiar drawings furnished by some of the respondents, and testimony in favor of such "forms" could easily be gathered. The individual bent, the dominant interest, the "apperception," as the psychologist would term it, serves as another clew. "A painter recalls his palette; a naturalist, his butterfly; a physician, his skull; a college student, his bicycle; in a few cases the entire ten drawings seem to be taken from "professional" suggestions. Another class of drawings seem to have their origin in the surrounding objects, being really copies of objects seen at the time; but this is a small class, and most of the images are doubtless drawn from the resources of past experience. Finally, the drawings are almost all simple in character. We draw what is easiest. This is well shown in the prevalence of faces seen in profile to the left, of left-handed spirals, and so on: for these are easier to draw, and the corresponding designs inverted towards the right; that is, easier for right-handed persons. So that these predominances indicate at once the general right-handedness of mankind, and the tendency to draw what is easiest.

The practical application of these facts tells severely against the arguments supported by the English Society for Psychological Research in favor of thought-transference. Dr. Minot points out that in several series of experiments reported in their "Proceedings" the position has been assumed that one kind of card, of number, of simple figure, is as likely to be thought of as another, and has estimated the improbability of the recorded coincidences accordingly. All evidence in which such an assumption is used must be looked upon with suspicion; and only when the conditions of the experiments take full and complete account of this very universal tendency for minds to run in similar grooves when dealing with simple things, will it be time to consider the evidence in favor of any abnormal form of the communication of ideas.

COMMERCIAL GEOGRAPHY.

An Agricultural Map of North America.¹

THE climatic conditions of North America are favorable to agriculture, except in the arid regions and in the extreme north. By the uncultivable region the agricultural land is divided into two parts of unequal extent,—the narrow Pacific coast strip, and the Atlantic region. East of the Rocky Mountains three zones of agriculture may be distinguished. The most southern one is that of subtropical cultures, reaching to the 37th degree of latitude; the central one is that of the culture of corn; and in the most northern zone wheat and oats are the principal products. On the Pacific coast there is no zone of subtropical cultures, but two zones only can be distinguished,—that of wheat, and that of oats. This fact shows that there is a marked difference between the Pacific and Atlantic regions. Two-thirds of the latter are used for the culture of subtropical plants, to which class corn belongs, while these are nowhere cultivated on the Pacific slope. This contrast is caused by the difference of climate, that of the wheat districts of California and Oregon being characterized by a uniform oceanic climate, with prevailing precipitations in winter, and dry summers; while the cotton and corn regions of the Atlantic side have a continental climate, with abundant precipitation during the warm seasons. Only the oats regions on the Pacific and Atlantic sides are analogous, the climate being characterized by a low temperature of summer and sufficient precipitation.

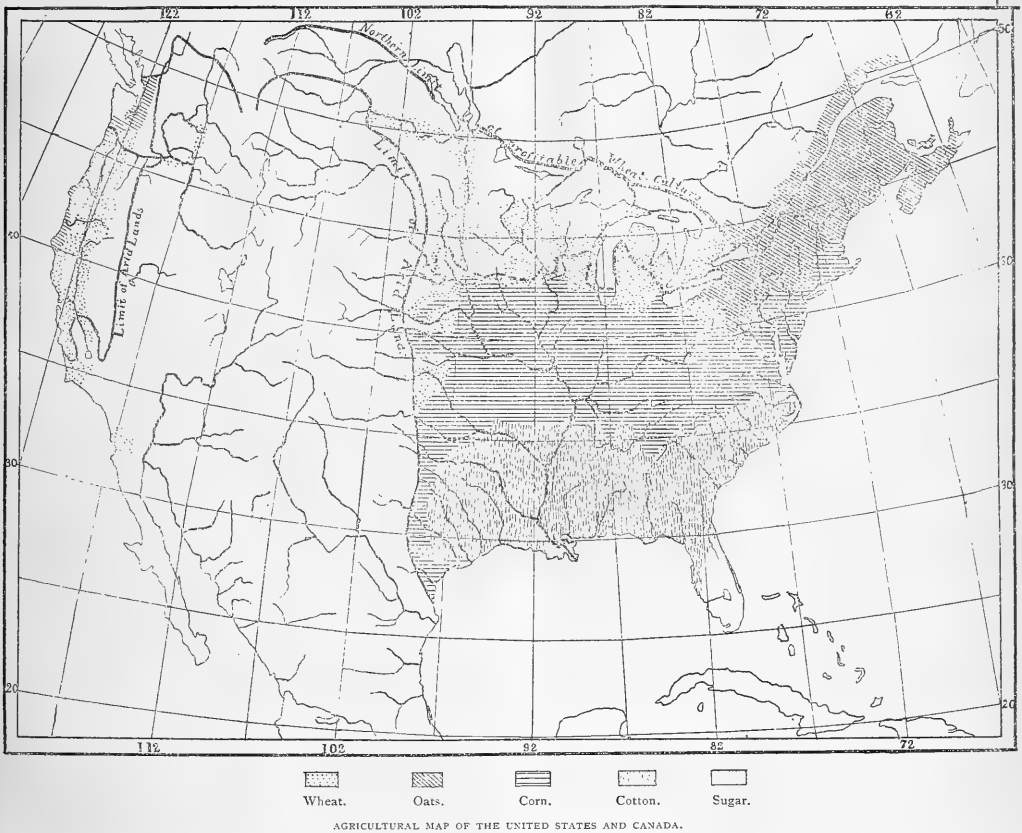

While the dampness and heat of the Atlantic summer favor the cultivation of subtropical plants more than in any other country, the sharp contrasts of summer and winter prevent the successful cultivation of plants of the southern temperate zones, especially that of the vine, oranges, and lemons, which require a spring with slowly rising temperature and moderate precipitation.

On the accompanying map the extent of each culture has been laid down according to the results of the tenth census, the percentage of area of land-occupied by each culture being inserted in a large-scale map, of which the present sketch-map is a reduction.

¹ According to Max Sering, *Die landwirthschaftliche Konkurrenz Nordamerikas*.

The area of cotton-culture has attained its present limits only after many attempts to introduce it still farther north, where early frosts prevent its being successfully carried on. At present the northern limit of cotton-culture approximately coincides with a mean January temperature of from 36° to 39° F. Even in the southern districts of cotton-cultivation, it is greatly influenced by the excessiveness of climate. While in the south of Spain the cotton-plant is a perennial, it is killed in the United States every winter by frost, and the plantations have to be renewed year by year. But the American plant exceeds, in amount and quality of its product, that of countries where the climate is more favorable to its growth. Besides cotton, corn is grown to a considerable ex-

We turn to considering the second zone of the Atlantic region, that of corn. In North America corn-culture extends farther north than in any other part of the earth. In more than two-thirds of the eastern part of the United States it is the principal cereal product. Its growth is favored by the heat and the suddenness of precipitation in summer, the sky being generally clear, while rain comes down during brief thunder-storms. The northern and western limit of corn-culture is not determined by the decrease of summer temperature and of precipitation, but by the increasing frequency of early frosts in the fall, and late frosts in the spring. In the valley of the Mississippi, corn ceases to be the most important culture under the 43¹/₂ degree of latitude, where the mean tem-

tent; but everywhere the former is the central point of interest to the farmer, more money and labor being invested in cotton-plantations than in any other culture. It is a remarkable fact, that corn, although the climate is well adapted to its growth, does not give nearly as good and rich harvests as farther north, where the climate is not so well adapted to its growth. The same is true regarding wheat, which gives the greatest and best returns near the northern limit of its possible cultivation. In the cotton region, wheat, barley, and rye are cultivated only in dry districts, in the higher parts of the Alleghanies, and in the semi-arid region of western Texas.

Sugar-cane is not cultivated very extensively, as the cold of winter hurts the young plants. It is only in the delta of the Mississippi that it is the prevailing culture, and in the adjoining parts of Louisiana it reaches a considerable extent.

perature of July amounts to 72°.5 F. In eastern Ohio and Pennsylvania it hardly reaches the 40th degree of latitude, and in the mountains of Virginia it does not extend beyond the 37th degree of latitude; while on the coast, where there are no late frosts, it rises to the 44th degree of latitude. North of this line, early varieties of corn are still cultivated, their northern limit being indicated on our map by a broken line. North of this line oats take the place of corn. In the West the corn region does not extend nearly as far north as in the East, on account of the greater frequency of late frosts, which the young plant is unable to withstand. The irregularity of the western limit is not caused by climatic differences, but by the recent settlement of the districts.

In this region wheat is cultivated extensively, but it is everywhere second in importance to corn. In the humid, warm regions of Delaware, in Tennessee, Kentucky, Missouri, Illinois, about three-

fifths of the whole region is used for corn-culture, while the northern and western limit covers those districts in which not more than one-half of the improved lands is used for this cereal. On the whole, the climate of the corn zone is not favorable to wheat, as the summers are too hot, and have too much rain. Notwithstanding this fact, the great centre of American wheat-production is situated in this region, south of the Great Lakes. It is remarkable, that, notwithstanding the great total amount of precipitation, excessive dryness in any part of the period of growth of the plant causes poor crops, long periods of clear weather being interrupted by sudden violent showers of rain. Besides this, the rapid increase of temperature in spring is not favorable to the development of wheat.

The northern zone is divided into two sections,—that of wheat, and that of oats. An important line in this region is the southern limit of summer wheat, as those countries in which only summer wheat can be grown have serious disadvantages as compared to others. As all the sowing has to be done in spring, the amount of work at this season is so great as to make the introduction of the most profitable methods of culture impossible. Owing to the severity of our winters, this line runs far more southerly than in Europe. Starting from Boston, it crosses Massachusetts, northern New York, and Ontario. It reaches the 45th parallel in Michigan, and in the prairie region descends to 38° and 39° north latitude. North of this line, only summer wheat can be grown. This region includes almost the whole arable prairie region, and the whole Dominion of Canada with the sole exception of southern Ontario. In the eastern portion this line coincides with a temperature in January of 18° F., while in the western part of the country it coincides with that of 30° F. This difference is principally founded on the difference of snowfall in those regions. While the Eastern States are covered with deep snow, the prairies have no such protection, and the dry, cold winds of winter kill the young plants.

One of the most remarkable features of the wheat area is its great extent northward in the central parts of our continent, where a clear summer favors its cultivation. The same climatic peculiarity accounts for the existence of the Genesee wheat region of central New York. Wherever the amount of precipitation in summer exceeds 50 centimetres, oats are cultivated in preference to wheat.

Finally we have to consider the Pacific coast strip. In the large valleys of California and Oregon the summers are warm, but not moist enough for the extensive cultivation of corn and cotton; while farther north the precipitation is sufficient, but the temperature too low. It is true that in a few districts of California, and also in Oregon and Washington Territory, corn is the third in importance among the cereal products; but, taken as a whole, only three per cent of the total area is applied to its cultivation. In southern California excellent crops of corn are obtained by means of irrigation.

In California and Oregon, and in that part of Washington Territory situated east of the Cascade Range, the culture of wheat is by far the most important. In California and Oregon seventy per cent of the cultivated area is used for growing wheat, a figure which is equalled only in Minnesota. The clear and dry summer favors wheat more than any other plant, a sufficient amount of humidity being retained in the ground after heavy winter rains. In southern California the cultivation of wheat requires irrigation. Second in importance is barley, which in California occupies twenty-three per cent of the cultivated area; farther north the rainfall increases, and oats take the place of barley; and still farther north barley-culture is more important than even that of wheat.

Taken as a whole, about one-half of the continent of North America is arable land, about thirty per cent belonging to the polar regions, while twenty per cent is arid land, or mountainous, rocky regions. The agricultural region includes one of the countries best adapted to the production of cotton and corn, while the climate of the same region excludes other cereals and the vine. The development of the wheat region, although very rapid, is hampered by numerous disadvantages,—severe winters, rapid increase of temperature in spring, sudden variations of temperature, late frosts in spring and early frosts in the fall, and frequent draughts impair its value, while the dryness of the early fall favors the culture. On the whole, the climate is not as favorable to the growth of wheat as that of Europe. If, notwithstanding this fact, the wheat-pro-

duction of the North-west has reached the enormous importance it has actually attained, the reason must be looked for in economic more than in agricultural considerations. The rapid colonization of the prairie regions, their easy cultivation, and the great natural highways of our continent, have given it the importance it possesses at present. But it would be erroneous to believe that this development will continue, that the amount of wheat produced and exported will indefinitely increase. When the tillable land has been taken up, and no new areas of productive land are added to the old ones, the economic reasons which have made the North-west the great granary of the world will cease, and the development will take another course, yielding greater returns from the same area than are possibly attained by the present wheat-culture.

NOTES AND NEWS.

THE director of the United States Mint, in his annual report to Congress, says that the gold product of this country for the year 1888, was 1,644,927 ounces, of the value of \$33,175,000. This is about the same as in 1887, being an excess of only \$175,000. The silver product was 45,783,632 fine ounces, of the commercial value of about \$43,000,000, and of the coining value of \$59,195,000. This is an increase of 4,515,327 fine ounces over the product of 1887. In addition to the product of our own mines, some 10,000,000 ounces of silver were extracted in the United States from foreign ores and bullion, principally Mexican. The coining of the mints during the year was as follows: gold, \$31,380,808; silver dollars, \$31,990,833; subsidiary silver, \$1,034,773; minor, \$912,201; total, \$65,318,615. The import of gold bullion and coin was \$11,031,941, and the export \$34,619,667, a loss by export of \$23,587,726. The import of silver was \$21,592,062, and the export \$29,895,222, a loss by export of \$8,303,160. The metallic stock of the United States Jan. 1, 1889, including bullion in the mints awaiting coinage, is estimated to have been, gold, \$705,061,975; silver, \$403,516,756; total, \$1,108,578,731.

—Dr. Chaillé, the well-known statistician, states that the average life of woman is longer than that of man, and in most parts of the United States woman's expectation of life is greater.

—A correspondent of the *New Orleans Medical and Surgical Reporter* says that petroleum-oil is almost universally used by the artisan and poorer classes in London as an illuminant, and the number of accidents which occur yearly with these lamps is very large. Mr. R. W. Brownhill has invented an ingenious prepayment gas-meter, based on the principle of the cigar, coffee, and other automatic supply-stands to be seen in every railway-station in London. It consists of a small attachment, which can be applied to any meter, and which will cause the gas to be delivered in definite quantities as paid for by pence dropped into a box. All that has to be done is to drop in a penny and pull a small handle, when sufficient gas for the supply of an ordinary burner for six hours will be delivered from the meter. Any number of pennies may be placed in the box, one at a time, up to 143, the handle being pulled after each penny, which would insure 858 hours' gas to one burner, or a shorter supply to several.

—Carl Zeiss, whose fame as a manufacturer of microscopes and microscopical lenses is world-wide, has just died at Jena, at the age of seventy-three.

—A flume fifty miles in length has just been completed at San Diego, Cal. It is intended for irrigation purposes and water-supply. The reservoir in the mountains, whence the water is supplied, is 4,500 feet above sea-level.

—Dr. O. J. Broch, at one time professor of mathematics at Christiania, and later minister of the Board of Trade in Norway, who more recently acted as director of the International Bureau of Weights and Measures at Paris, died at Sèvres, Feb. 5, at the age of seventy-one. It has been the especial duty of the Bureau, over which Dr. Broch presided from its creation after the Metric Convention of 1875, to construct new standards of the metre and kilogram for the different countries which were parties to that convention. At the time of his death all these standards had been constructed, and were only awaiting final approval at Sèvres before their delivery this year to the several contracting States.

— Agassiz Association, Chapter 949, New York City (Z), held its third annual exhibition of natural history collections, microscopes, electrical apparatus, etc., on Saturday, March 2, 1889, at 49 West 20th Street, near Sixth Avenue, from 3 to 6 P.M., and from 7 to 10 P.M.

— The ship-canal which is to connect Manchester, England, with Liverpool, is being rapidly constructed, ten thousand men and a great number of steam excavators being engaged upon it. The canal will be thirty-five miles long, twenty-six feet deep, and a hundred and twenty feet wide at the bottom.

— Rev. Arthur C. Wagborne, New Harbor, Newfoundland, has published "A Summary Account of the Wild Berries and other Edible Fruits of Newfoundland and Labrador."

— The exercises of the centennial celebration of Georgetown University, Washington, D.C., closed, Feb. 22, with a session in Gaston Hall, at which the honorary degrees were conferred by President Cleveland. Three gold medals were struck in honor of the occasion, which were awarded as follows: one to John Gilmory Shea, LL.D., the historian of the Catholic Church in America, for his work, "The Life and Times of Archbishop Carroll;" a gold medal, struck by the Alumni Association, presented to his Eminence James Cardinal Gibbons, for the archi-episcopal see of Baltimore; and a gold medal, like the preceding, to the President, Grover Cleveland, for the Government of the United States.

— A meeting was held, Jan. 31, in the meeting-room of the Royal Society, London, the Right Hon. Lord Rayleigh, Sec.R.S., in the chair, for the purpose of promoting a project, set afoot by some of the leading men in Munich, of erecting in that city a statue of George Simon Ohm, — a man who, although he discovered no new phenomena of very striking importance, yet by the accuracy of his thought, and the clearness of his insight into the true bearings of physical facts, was able to lay one of the principal and firmest parts of the foundation of modern physics. The occasion for the proposal at this particular time is the near approach of the hundredth anniversary of Ohm's birth, on March 16, 1789.

— The fourteenth annual commencement of the American Veterinary College was held at Chickering Hall, New York, Monday evening, March 4.

— At the meeting of the Royal Meteorological Society, Feb. 20, a report on the helm-wind inquiry was made by Mr. W. Marriott, F.R. Met. Soc. The helm wind is peculiar to the Cross Fell range of mountains in Cumberland, which runs from north-north-west to south-south-east. This range is high and continuous, and is not cut through by any valley. Cross Fell is 2,900 feet above sea-level. From the top of the mountains to the plain on the west, there is an abrupt fall of from 1,000 to 1,500 feet in about a mile and a half. At times, when the wind is from some easterly point, the helm forms over this district, the chief features of the phenomenon being the following: a heavy bank of cloud rests along the Cross Fell range, at times reaching some distance down the western slopes, and at others hovering just above the summit, while at a distance of two or three miles from the foot of the fell a slender roll of dark cloud appears in mid-air, and parallel with the helm cloud; this is the helm bar. The space between the helm cloud and the bar is usually quite clear, while to the westward the sky is at times completely covered with cloud. The bar does not appear to extend farther west than about the river Eden. A cold wind rushes down the sides of the fell, and blows violently till it reaches a spot nearly underneath the helm bar, when it suddenly ceases. The observations that have been made in the district during the past three or four years show that the helm wind is not such a rare occurrence as it was popularly supposed to be, the bar having been observed on 41 occasions in 1885, 60 in 1886, and 19 in 1887. The phenomenon takes place usually when the sky to the eastward is covered with cloud.

— Two large hydraulic canal-lifts have been recently erected at Fontinettes, on the Neufossé Canal, in France, and at La Louvière, on the new Central Canal, in Belgium. They both consist of two counterbalancing troughs, resting on central hydraulic rams, 6 feet 6½ inches in diameter, and moved by an excess of water introduced into the upper trough, and by hydraulic machinery supply-

ing water to the presses under the rams to aid the ascent. The troughs at Fontinettes are each 129 feet 7 inches long, 18 feet 4½ inches broad, and contain 6 feet 6½ inches depth of water, so as to be available for vessels of 250 tons. The troughs at La Louvière are 141 feet long, 19 feet wide, and hold water to a depth of 10½ feet, being designed to admit vessels of 400 tons. The total weight they lift is 785 tons at Fontinettes, and 1,037 tons at La Louvière, while the heights of the lifts are 43 feet and 50½ feet respectively.

— Professor Baker of the Illinois University says in a letter to the *Clay Work* on the sustaining strength of brick-work, "By actual experiments in a testing-machine, the average strength, from fifteen experiments, of piers laid in ordinary brick and common lime mortar, using the same care as that with which ordinary brick masonry is built, stood a few pounds (I am writing from memory) over 1,500 pounds per square inch, which is equal to 216,000 pounds per square foot, or the weight of a column of brick 2,000 feet high; with ordinary Portland cement mortar, the strength was, for a mean of eight experiments, 2,500 and some odd pounds per square inch, which is equal to 360,000 pounds per square foot, or the weight of a column of brick masonry 3,600 feet high."

— The naval board charged with the duty of supervising and reporting upon the test of the 15-inch pneumatic gun last January have just made their official report to the secretary of the navy, who pronounces it satisfactory. The report is to the effect that more than one-half the projectiles, fired at ranges of 300, 1,700, and 2,100 yards, fell within the specified target limits, an area of fifty by a hundred and fifty feet.

— The annual address of the president of the New York Microscopical Society, Charles F. Cox, read Jan. 4, 1889, was on "The Spontaneous Generation Theory, and its Relation to the General Theory of Evolution." The close of the address was as follows: "In the domain in which Mr. Darwin worked, I look upon natural selection as a well-established principle. In the developmental idea as extended and expounded by Herbert Spencer, I find much that appeals strongly to my sense of fitness and consistency, and, if possible, I could see the hypothesis become a proven law of nature without a shock to my mental or moral status. I have no fear of anything that is true. But what I have endeavored to show is, (1) that a transition from not-living matter to living forms is an essential step in the process of evolution; (2) that at the point at which experimental proof is applicable (namely, to present and continual archeobiosis), the theory of such a transition is discredited, if not disproved; (3) that scientists generally accept this conclusion, and that those who are not thorough evolutionists are confined to the mere belief that the step from the not-living to the living was taken at some remotely early period, beyond the reach of evidence. And finally, I submit, as a consequence of these premises, that the general theory of evolution is still in the stage of hypothesis, and that in the gap between lifeless substances and living forms we have the veritable 'missing link.'"

— Thanks to strict preservation, and to the fact that the inhabitants are realizing the value of the bird, according to *Nature*, the eider has greatly increased in number in Iceland during recent years. The people do all in their power to attract the bird to their property. Among these attractions are bells worked by the wind or by water, the hanging-up of dress material of a glaring color, and the keeping of brightly colored fowls. A society has been formed for the granting of premiums for the killing of animals preying upon the eider, and last year 1,155 such prizes were awarded.

— In a late number of *L'Architecture*, M. Edmond Pottier contributes a letter on antique polychromy, combating the idea that a Greek temple was an edifice painted in every part, from the steps to the cornice, which appears to be entertained by some French archæologists. He observes that no monument, except the temple at Ægina, offers traces of color on the shafts of the columns, and that a comparison cannot be instituted between that case and such a building as the Parthenon, inasmuch as the latter was in marble and the former in porous stone, to which it might have been thought desirable to give a surface finish of paint, without implying that the same treatment would be applied to marble.

THE NEW YORK MINERALOGICAL CLUB is a society organized in 1887 for the purpose of studying the rocks and minerals of the city and vicinity, which present many interesting and remarkable features. Very few persons have any idea of the number and variety of minerals that are found in the rocks of Manhattan Island and the immediate suburbs. But in some respects this locality is peculiar, for the reason that while a large amount of excavation and rock-cutting is all the time going on, yet scarcely is a deposit of minerals discovered in the progress of any such work, ere it is built over or filled up, and rendered forever inaccessible. New York Island specimens, therefore, possess in this aspect unusual interest, and the collection and preservation of them become a matter not only of scientific value, but of local pride. During a number of years past, a gentleman well known, and greatly respected in cultured circles here, Mr. Benjamin B. Chamberlin, has devoted a great amount of time, labor, and care to gathering these specimens from all parts of the city, wherever excavations were in progress. At the time of his death, in October last, he had thus secured the finest cabinet of New York minerals ever obtained. Mr. Chamberlin was not a man of wealth, and labored in this field out of pure love for science. The New York Mineralogical Club is very desirous to obtain this collection by purchase, that it may be retained in the city in its entirety, and serve as the foundation of

a permanent local collection, which, for the reasons above given, must ever increase in value and interest as time goes on and the city is more and more built up. The moderate sum of fifteen hundred dollars will secure this very desirable object; and the trustees of the American Museum of Natural History have agreed to receive the collection on permanent deposit in their absolutely fire-proof building, where it will always be accessible for purposes of study, — a monument to the zeal and success of its honored collector, and a matter of interest and credit to the metropolis.

SCIENCE IN THE SCHOOLS.

THE committee on the subject of science in the schools, of the American Society of Naturalists, consisting of Samuel F. Clarke (Williams College), William North Rice (Wesleyan University), William G. Farlow (Harvard University), George Macloskie (College of New Jersey, Princeton), and C. O. Whitman (editor *Journal of Morphology*), have made a report which has been accepted and heartily approved by the society. The committee have been retained, and have been granted full power to act for and with the society in the endeavor to establish what they have recommended.

From the steadily increasing demand of scholars, parents, and teachers for more and better instruction in these departments, the committee feel assured that the time is ripe for this movement, and that it only needs intelligent and concerted action to produce the results desired. The society will be represented at the meetings of the various educational associations in the country, and will make every effort to push the movement as vigorously as possible. It needs, however, and asks for, the active support and encouragement of every parent and teacher who believes that the young should have their natural tendencies, and longings for a knowledge of the things of nature, cultivated; their questions about things which are in every way pure and true answered; opportunities for enjoyment, and for friendships that will never fail, laid open to them; and, above all, the opportunity freely afforded them for securing the brain-growth and mental power, by observation and independent thought, which these studies are so peculiarly well fitted to give.

In regard to the general topic of science-teaching in the schools, the committee believe the following propositions fairly formulate the views which are held by the members of the society, and which the society should use its influence to diffuse:—

1. Instruction in natural science should commence in the lowest grades of the primary schools, and should continue throughout the curriculum.

2. In the lower grades the instruction should be chiefly by means of object-lessons; and the aim should be to awaken and guide the curiosity of the child in regard to natural phenomena rather than to present systematized bodies of fact and doctrine.

3. More systematic instruction in the natural sciences should be given in the high schools.

4. While the sciences can be more extensively pursued in the English course in the high schools than is practicable in the classical course, it is indispensable for a symmetrical education that a reasonable amount of time should be devoted to natural science, during the four years of the high-school course, by students preparing for college.

5. An elementary (but genuine and practical) acquaintance with some one or more departments of natural science should be required for admission to college.

Believing that the propositions stated above will command general acceptance, they are aware that there must be difference of opinion, among the members of the society and among intelligent educators in general, in regard to details, and that the precise subjects to be introduced into the curriculum must vary somewhat with the circumstances of different localities. They offer the following, not as necessarily the best scheme, but as a reasonable and practical scheme, which may at least serve to illustrate the general principles which they have formulated.

In the primary schools, and in the lower grades of the grammar schools, they recommend that the study of plants and animals should be the main part of the scientific work. The botanical

instruction should commence with such simple exercises as drawing and describing different forms of leaves, and should gradually advance to the easier and more conspicuous flowers, and later to the more obscure and difficult forms of flowers, the fruits and seeds.

The zoological instruction in the lower schools should not attempt a systematic survey of the whole animal kingdom, but attention should be directed chiefly to the most familiar animals, and to those which the pupils can see alive. The common domesticated mammals should first be studied, and later the birds, the lower vertebrates, the insects, crustacea, and mollusks. While the range of zoological instruction must be limited as regards the number of forms studied, those few familiar forms should be so compared with each other as to give the pupils, very early, some conception of the main lines of biological study,—morphology, physiology, taxonomy.

Special prominence should be given to the study of plants and animals which are useful to man in any way; and the teacher may advantageously, from time to time, give familiar talks in regard to useful products of vegetable and animal origin, and the processes of their manufacture.

Attention should also be given to the more obvious characteristics of the kinds of minerals and rocks common in the region in which any school is situated, and to such geological phenomena as are comparatively simple and easily observed.

A most important feature of the scientific instruction in the lower grades should be to encourage the pupils to collect specimens of all sorts of natural objects, and to make those specimens the subject of object-lessons. The curiosity of the children will thereby be rationally cultivated and guided.

The subject of human physiology and hygiene is of so immense practical importance, and so few comparatively of the pupils ever enter the high school, that we regard as desirable some attempt to teach the rudiments of the subject in the grammar, and even in the primary schools.

They recommend the introduction of exceedingly rudimentary courses in physics and chemistry in the highest grades of the grammar school, and further, as perhaps the most desirable branches of science to be included in the classical courses in the high school, and to be required for admission to college, physical geography, phænogamic botany, and human physiology. The first is suggested as tending to keep alive in the student's mind a sympathetic acquaintance with nature in its broader aspects; the second, as affording unequalled opportunities for discipline in observation; the third, as affording knowledge of the greatest practical importance.

The rudiments of physics and chemistry, which they propose for the grammar schools, will enable physical geography and physiology to be intelligently studied in the early years of the high-school course.

For the scholars in the English course in the high school, there will naturally be more advanced and systematic instruction in chemistry, physics, and zoology, and also instruction in geology and astronomy; but the classical students may with propriety leave these studies until they reach them in the college course. The scientific instruction they will have received in the primary and grammar schools, and the study of the three branches above specified in their high-school course, will be sufficient to preserve that natural and wholesome sympathy with nature the loss of which is now the main obstacle to the successful study of natural science in the colleges.

THE COAL QUESTION IN ENGLAND.

MR. R. Price Williams, M.Inst.C.E., read a paper on the "Coal Question" at the meeting of the Royal Statistical Society on Feb. 19. The following is an abstract of the paper as given in *Engineering* :—

After paying a well-deserved tribute to the labors of the late Professor Jevons in connection with this subject, the author shows, by a series of tabular statements and diagrams, the rapid increase in the coal-production of England prior and subsequent to the date of the coal commission in 1871. The Northumberland and Dur-

ham coal-field, as is pointed out, still gives to Newcastle its pre-eminence as the chief source of the coal-supply, the output last year from Durham alone amounting to over 28,750,000 tons, or to more than one-sixth of the total production in the United Kingdom. Attention is drawn to the fact that during the last four or five years there has been a considerable decrease in the output from these northern coal-fields; and the maximum limit of the coal-production it is considered has been reached, and henceforward it will continue to decline. It is shown, that, at the average rate of increased production during the last twenty-two years, the 9,294,000,000 tons of available supply would be entirely exhausted in about ninety-four years.

The author devotes a considerable part of his paper to the South Wales coal-field,—a district he is well acquainted with,—and attention is directed to the remarkable development which has occurred during the last few years in the South Wales steam coal-trade, the 26,000,000 tons produced last year coming next in amount to that of Durham. This large quantity is shown (after allowance is made for waste in working) to represent about 5,381 acres of a four-foot-thick coal-seam practically worked out in the course of a single year. The total available supply in the South Wales coal-basin is estimated by the coal commissioners at 36,566,000,000 tons, or just one-third of the whole available supply in the United Kingdom, which, at the rapid rate of increased production which has obtained during the last quarter of a century, would, as the author shows, be entirely exhausted in the short space of seventy-nine years.

The rapid development in the coal-production in the eastern division of this coal-field, which contains the famous steam coal-measures, is strikingly shown by the enormous growth of the coal-exports from Cardiff, more especially to foreign countries. In 1864 these only amounted to 1,500,000 tons, doubled in the next ten years, and again doubled in the following seven years; while in 1887 they amounted to 8,250,000 tons, or to more than a third of the entire coal-exports for the United Kingdom for that year.

Two-thirds of the South Wales coal-supply is obtained from Glamorganshire, more particularly from the eastern division, containing these valuable steam coal-seams. The author shows, that, if the production from this eastern portion of the coal-basin continues to increase at the average rate it has done during the last twenty-four years, the whole available supply, which the coal commissioners estimated at 12,963,000,000 tons, will be entirely worked out in the course of the next sixty years; and the portion containing the lower or steam coal-seams, in the short space of forty-two years.

The coal exported from Cardiff, consisting chiefly of this high class of coal, the author points out, represents, after making allowance for waste in working, about seven acres of the famous four-foot steam coal-seam entirely worked out during each working day of the year.

The coal-productions from all the other principal coal-fields are separately dealt with; and the dates at which, at the average increased rate of output during the last twenty-four years, they will become exhausted, are given in the following summary:—

	Years.
Northumberland and Durham	94
South Wales	79
South Wales (eastern division)	46
Lancashire and Cheshire	74
Yorkshire, Derbyshire, and Nottingham	90
Warwickshire	53
Denbighshire and Flintshire	250
Scotland	92
United Kingdom	102

Under the head of coal-consumption, particulars are given of the chief uses to which the coal is applied, from which it appears that the coal consumed in the manufacture of pig iron, and in the manufacture of merchant iron and steel of various kinds, amounted at the time of the coal commission to nearly one-third of the coal produced in the United Kingdom. The large economies since effected by the Bessemer, Siemens, and other processes, are shown, however, to have reduced the consumption in 1887 to little more than 16 per cent of the coal-production. Attention is drawn to the large economies effected and to be effected by the use of compound

engines for steam navigation and locomotive purposes. The amount of coal used by ocean-going steamers during 1887 amounted to nearly 7,000,000 tons, and that consumed by the much larger number of steamers engaged in the coasting trade is estimated to have equalled that amount. The coal consumed by the locomotives on the railways in England in the same year is shown to have exceeded 6,000,000 tons.

Particular attention is drawn to the very rapid growth of the export of coal, which has increased from 4,333,333½ tons in 1854, to over 27,000,000 in 1888. The author considers it is but the measure of increased commercial prosperity, and that to impose any tax upon such exports would be like killing the goose that lays the golden eggs.

The author, in his concluding remarks, observes, that, if the growth of the trade and prosperity of England is to continue as it has done in the past, its coal-production, which is at once the cause and effect of this growth, must necessarily keep pace with it; and it is pointed out that unless large economies, which can and ought to be effected in its consumption, are realized, all the largest and best sources of the coal-supply will be exhausted in the very short periods mentioned in this paper. The hope is expressed, that, by drawing attention to this most vital subject, further strenuous efforts may be made to husband English coal resources in every possible way, and to put a stop to the great waste in working the mines, and in the consumption of coal generally.

MINING INDUSTRIES IN SIAM.

SIAM is rich in minerals. Gold, iron, tin, and copper are found in many parts of the country; but the want of roads, and consequent difficulty of getting these metals to market, prevent their being worked, except for the limited wants of the natives.

The English consul at Bangkok, Mr. Child, says, in his last report, an abstract of which appears in the *Journal of the Society of Arts* for Feb. 22, that the eastern part of Siam is very rich in iron, antimony, and argentiferous copper and tin. It is from the provinces of Petchaboon and Löm that the cutlasses, spears, and knives are furnished to all the provinces of the north and east. Silver is not found in Siam.

As regards gold, this metal is found in many places, but the mines at Bang Tapan on the west coast are said to contain the purest gold in the country. They have been worked by the natives by simply turning over the ground, the gold being found in the shape of nuggets. When nuggets over a certain size were found, the miners were obliged to hand them over to the government, but they were paid for the same according to a tariff fixed by the authorities.

A syndicate of foreigners has been formed, with a concession from the king, for working these mines, and has now a number of workmen employed, the prospects for rich developments being good.

The quartz-mines of Muang Krabin, although productive, were declared unprofitable to the government. Experienced engineers from Australia, mining machinery of recent invention, immense upright pumps and other hydraulic machinery, and a narrow-gauge railroad with rolling stock for the conveyance of the product, had been procured for the working of the mine; but, the organizer of the great scheme having been decapitated for alleged treason, the whole of the plant is lying idle.

The royal metal of Siam is mostly manufactured into vases, teapots, betel-boxes, and other articles, which it is the custom of the kings of Siam to present to subjects upon their elevation to high rank in the peerage of the kingdom. They are looked upon in a sense as insignia of their exalted rank, the shape and style of the set denoting the standing of the beneficiary.

It is impossible to procure statistics concerning the output of the mines. Iron of good quality is found in the eastern provinces, but it is worked in a very crude and primitive manner. Foundries are unknown. A hole or pit having been dug close to the mountain, the miner collects and piles up his ore, which he smelts with charcoal. The molten metal is deposited in a cavity prepared for its reception, and when cold the product is carried home.

There a fire is prepared, which is kept alive by a bellows made of two trunks of hollow trees buried in the ground, and having two long sticks as handles. A child works the bellows, while husband and wife or son hammer the iron into shape.

The knife, cutlass, spear, or agricultural implement produced by this combined labor finds a ready sale throughout the north of Siam, and, although the workmanship is poor, it suits the requirements of that section. The locality of the mines preclude shipments to Bangkok, as it would have to be conveyed to the river on elephants,—a method of conveyance too expensive for the commodity.

Tin is found in profusion in the Malayan peninsula, and is worked by Chinamen. It is generally exported direct to Singapore from the locality in which it is mined. Tin is also found in eastern Siam to a limited extent, but none of it finds its way to the capital.

Copper is found in certain localities, especially in the eastern provinces,—Champasak, Petchaboon, and Löm. In the former province, on the Makong River, there is a place where the natives procure the finest metal, of which they make a coin that passes current in that locality. It is about two inches in length, a quarter of an inch in breadth, and shaped like a canoe. The province adjoining that has an iron coin of the same shape, but larger in size. Virgin copper is held in great esteem by many for certain qualities it is supposed to possess when employed as an agent in transmuting metals. Without it as a basis, the native alchemists claim that gold cannot be obtained.

Coal is found on the coast and in the interior, but cannot be utilized. Limestone is brought to Bangkok from the interior. The lime is mixed with turmeric, and is used to a large extent by the Siamese in combination with the betel-nut and *seri* (pepper-leaf).

Precious stones come principally from the province of Chantibun; rubies, sapphires, topaz, asterias, and other stones being found in that district. The diamond is unknown as a native stone. The sapphire mines to the south of Chantibun, to which thousands of Burmese flocked a few years ago, have been exhausted.

BOOK-REVIEWS.

Popular Lectures and Addresses. By SIR WILLIAM THOMSON. In 3 vols. Vol. I. Constitution of Matter. London and New York, Macmillan. 12s. 3s.

THE author of this work possesses in an eminent degree the ability of putting into untechnical language those essentials of knowledge which are most interesting and attractive, and at the same time most useful, to the general reader. Among the contents of this volume may be mentioned "Capillary Attraction," which was originally delivered as a lecture before the Royal Institution in 1886; to which are added three appendixes treating of certain curious motions observable on the surfaces of wines and other alcoholic liquors, gravity and cohesion, and the equilibrium of vapor at a curved surface of liquid.

Shortly after the delivery of this lecture, it was suggested to Mr. Thomson that it might be advisable to make it more conveniently accessible to the general public than it could be in the "Transactions of the Royal Institution;" and it was accordingly arranged to bring out, as one of the Nature Series, a small volume containing the lecture mentioned, together with several other papers pertinent to the subject. While the volume was in course of preparation, it was decided to increase the size of it, adding several other lectures and addresses to the contents, and make it the first of a series of three volumes, constituting a reprint, in a revised form, of all Sir William's popular lectures and addresses. The result is the volume before us, the first volume of the series.

Besides the lecture already spoken of, a chapter each is devoted to the following subjects: "Electrical Units of Measurement," "The Sorting Demon of Maxwell," "Elasticity viewed as possibly a Mode of Motion," "The Size of Atoms," "Steps towards a Kinetic Theory of Matter," "The Six Gateways of Knowledge," "The Wave Theory of Light," "The Age of the Sun's Heat," and "Electrical Measurement." These were originally delivered as lectures and addresses before the Royal Institution, the Institution of Civil Engineers, the British Association, and the Franklin In-

stitute of Philadelphia. The chapter on "The Age of the Sun's Heat" is reprinted from *Macmillan's Magazine*, and consists of three parts, treating respectively of the secular cooling of the sun, the sun's present temperature, and the origin and total amount of the sun's heat.

The Psychic Life of Micro-organisms: a Study in Experimental Psychology. By ALFRED BINET. Tr. by Thomas McCormack. Chicago, The Open Court Publ. Co. 12°. 75 cents.

IT may, perhaps, not be rash to venture the statement that in no field of study has the introduction of the comparative method been so helpful as in the study of mental phenomena; of the coordinations between the organism and the environment. It is this that has widened the horizon of the psychologist from the observation of his own individual, adult, civilized consciousness, to the observation of other men and of other races in different stages of civilization, of other ancestries, of other no less interesting though more lowly forms of life, of the embryonic, immature stages of development. It is to the apparently most insignificant group of such phenomena that M. Binet devotes his monograph,—to the psychic life of the lowliest denizens of the earth, forms so simple that even the distinction between animal and vegetable becomes doubtful when their classification is attempted. Many a reader would perhaps be likely to think that an account of the psychic life of micro-organisms might be as brief as that celebrated essay on the snakes of Greenland, which was all contained in the sentence, "There are no snakes in Greenland." M. Binet shows most conclusively, however, that there is psychic life in these unicellular specks of protoplasm; that they exhibit relations to their environment similar in kind, though vastly inferior in degree, to those to which we unhesitatingly attribute an intellectual origin, when we observe them in ourselves or any of the higher animals.

M. Binet classifies these evidences of embryological mental activity into (1) those connected with motion and sensation, (2) those connected with nutrition, (3) those connected with reproduction, and (4) those connected with "social relations." Under the first head we observe that the *Didinium nasutum* (a type of the ciliated infusoria) has the power of reversing its motion, of arresting it, and that for this purpose it makes use of a perfect miniature steering apparatus. We note, too, that the most rudimentary sensation is that of contact, many of these microscopic animals having no other; that after this, sight develops, it being not improbable that certain vegetable forms possess the analogue of an eye. The *Didinium* has vision enough to hurl a shower of darts at its prey, thus paralyzing it, and making it an easy victim; while the *Euglena* are sufficiently sensible to color to constantly congregate between the lines F and G of the solar spectrum. The maintenance of life is always the result of a re-action to the environment, and in this "life of relation" a psychic element must enter. In the motions necessary to seize the prey, in the power of selection that enables the organism to seize certain particles and reject others, we have a rudimentary form of choice. In the recognition of the position of the desired food, M. Binet does not hesitate to detect an elementary space-perception. The excitement preceding the times for copulation shown by unicellular organisms suggests an analogue to the emotions. Under the fourth head belongs the formation of a group of cells into a colony, in which the individuals act harmoniously, and each contributes to the general welfare.

These are only a few of the very suggestive observations and comments that M. Binet brings together; and if from the rest of the work a single example of the possibilities this study reveals must be selected, it should be the experiments of Professor Pfeffer on the spermatozooids of ferns. This observer finds that when a solution of malic acid is held in a tube, and a similar solution of one-thirtieth the strength be placed in a watch-crystal in which are the spermatozooids, the latter will leave the watch-crystal for the tube; and not only this, but when the solution in the tube is only twenty times as strong, these organisms remain unaffected. It seems to be the ratio of the intensities of the two solutions that brings about the result, and in this Professor Pfeffer sees an undoubted analogy to the psychophysical law illustrated in the power to distinguish between sensations as tested by Weber, Fechner, and

others. If this law can be thus corroborated, it is a wonderful law indeed.

The general position of M. Binet is thus somewhat in opposition to current views. He combats the view that in the unicellular organisms we have a simple and blind mechanical reflex action between irritable substances and an irritating environment, but holds that rudimentary forms of various psychic functions take their origin here. He pronounces Mr. Romanes' attempt to fix the grade at which the several constituents of psychic function enter into play as artificial and arbitrary, and believes that a more complete study of these lowliest forms of life will establish a more rigid and scientific criterion of mind, and show the substantial unity and primordially of the psychic element. It is certainly a long step from the days when man was defined as a rational animal, denying by inference, to the rest of creation, a share in this possession, to the days when what we can see only with the aid of the most improved results of science is pronounced akin to the most human part of man.

AMONG THE PUBLISHERS.

THE *Atlantic* for March contains an article by Stuart F. Weld, on "The Isthmus Canal and Our Government," which will interest students of politics. The author is strongly in favor of placing the canal under international control, as the Suez Canal has already been placed; and he shows, by quotations from public documents, that our own government has always been in favor of such control, except during a brief period beginning with the administration of President Garfield. Another article of interest is "Personal Reminiscences of William H. Seward," by Mr. and Mrs. Samuel J. Barrows. Mr. Barrows was for a time private secretary to Mr. Seward at the State Department, and during an illness of some months his wife took his place. Hence they have much to tell us about the statesman's official and private life, and they tell it in a simple and pleasant way. Mr. John Fiske continues his articles on American revolutionary history, treating in his usual excellent style of "Ticonderoga, Bennington, and Oriskany." The *Atlantic* has also a paper on "Some Colonial Lawyers and Their Work," by Frank G. Cook, which lawyers will like to read, and the usual variety of lighter articles.

— Mr. John Delay of this city has begun the publication of a series of Gleanings from Foreign Authors, the first number of which now lies before us. It contains "A Love Match," translated from Ludovic Halévy, and "King Apepi," by Victor Cherbuliez. The former is a very pleasant little love-story told by the lovers themselves in extracts from their diaries, which they read to each other after their marriage. The other is less agreeable as a whole, but ends in an amusing and unexpected way. We are not told whether the whole series of which this book is the beginning is to consist of novels, but they will doubtless constitute the greater part; and, if the other volumes are up to the level of this one, they will make an addition to the lighter literature of English readers.

— *Outing* for March is a sporting number. We note the following principal articles: "Fox-Hunting; A Day in the Shires," by Henry H. L. Pearse; "Lawn Tennis in the South," by Henry W. Slocum, jun.; "Snowshoeing in Canuckia," by James C. Allan; "Salmon-Fishing on Loch Tay," by "Rockwood," and illustrated by J. & G. Temple; "Spaniel-Training," by D. Boulton Herral; "How to Cycle in Europe," by Joseph Pennell; "Amateur Photography," by Ellerslie Wallace; "Winter Shooting in Florida," by F. Campbell Moller; and "Coaching and Coaching Clubs," by Charles S. Pelham-Clinton.

— A catalogue of the contents of the *Magazine of American History* for March reveals great current interest. The leading article describes the "Historic Homes and Landmarks" about the Battery and Bowling Green, New York City. The whole procession of Dutch and English governors who resided in the old historic fort opposite the Bowling Green are passed in review, as well as those who lived in the house built for Washington on the same site. One of its features is the sketch of the site of the City Hotel, of

which so little is generally known. The second article, "America: the World's Puzzle in Geography," is a study by Rev. William Barrows, D.D. President James C. Welling, of the Columbian University, Washington, D.C., replies to Gen. Wilcox in an article on "The Mecklenburg Declaration of Independence;" the well-known author, J. G. Rosengarten, contributes "Du Pont De Nemours;" Gen. Alfred E. Lee discourses upon "German Family and Social Life;" Mr. Maturin L. Delafiel writes of Col. Henry Beekman Livingston; and Annie E. Wilson gives an authoritative paper entitled "Thrilling Adventure of a Kentucky Pioneer."

—"The Century Dictionary" is to contain some features new in dictionaries, one of which is the entry of every thing in the one alphabetical order, abbreviations and foreign phrases as well as common words. While the plan of the work excludes biographical and geographical names, yet such adjectives as "Chinese," "Darwinian," etc., derived from proper names, will find place, and be fully defined. A great point with the new dictionary is its encyclopedic treatment of words. It will not stop at definitions, but is said to go into particulars about things to a greater extent than any other book except an encyclopaedia, and it gives the information in a condensed, usable form. Such terms as "Bright's disease," "Tweed Case," "electric light," etc., are defined under the words "disease," "case," "electric," etc. Under "case" there are twenty-seven entries of such terms as "Dred Scott Case," "Tichborne Case," etc., in addition to the etymologies and definitions usually to be found in a dictionary. Such terms as "credit mobilier," "bankruptcy laws," "crossed checks," "clearing-house system;" the names of foreign administrative divisions, such as "arrondissement;" legislative bodies, like the "Cortes" and "Bundesrath;" parties and classes, such as "Anarchist," "Nihilist," "Chartist," "Fenian," "Carbonari," etc.—will be fully defined in "The Century Dictionary;" and it is even understood that the new use of "barrel" ("the money, especially when the sum is large, supplied by a candidate in a political campaign for campaign purposes, but especially for corrupt purposes, etc.") has found a place.

—In the twenty-four years since the late Mr. N. Trübner began to carry out, under the title of *The American and Oriental Literary Record*, the idea of supplying periodically, not only lists of books published in the various countries of the East and throughout the whole of the American continent, as well as of European works bearing upon those countries, but also literary information on books and their authors, the value and usefulness of the *Record* have been fully recognized throughout the literary world. The growing importance and rapid spread of scientific research in the United States on the one hand, and the ever-increasing interest which literary men in England take in the history, antiquities, and civilization of the East on the other, have made it appear desirable to the publishers to expand the original design of the *Record* by assigning ample space to literary and scientific articles on subjects within its scope. They are making this departure with the greater confidence of success, as there is no other periodical in the English language which offers such a solid and comprehensive programme; and, while they invite the co-operation of scholars in the special departments to which their studies are directed, they look forward for continued support to the literary public generally, who have for so many years accorded to the *Record* their signal approbation and patronage. With a view to securing, as far as practicable, the indispensable superintendence by a competent and experienced editor, of the Oriental section of the expanded issue, they have made arrangements with Dr.rost, of the India office, to undertake the editorial management; and they are confident, that, in intrusting this department to his care, they can rely upon its being directed with impartiality and independence of judgment. In addition to personal notices, such as obituaries and literary notes of works projected or in progress, the publishers intend to devote more space to reviews, independent articles on Oriental subjects, and more especially to periodical statements as to the advance made in the various fields of Oriental research, so as to make the *Record* a depository of information concerning the current state of Eastern literature in all its branches. It is proposed as a first and tentative venture to issue six numbers

annually, which will be published regularly in the middle of every alternate month, each issue to be a full record of the events of the two preceding calendar months. But the publishers hope that they will soon be enabled to issue the *Record* monthly. This, of course, will depend upon the success of their venture. The price of the new series, the first number of which will appear on the 15th of March, 1889, will be ten shillings per annum, payable in advance, or two shillings per number.

—The *Electrical World*, March 2, says: "Last week we reached our highest water-mark, up to that time, in an issue of 72 pages, the size and contents being such as to bring in upon us overwhelming congratulations from friends and readers all over the country. Marking as it did the close of our fifteenth year, the issue was naturally taken as a good exemplification of the great growth of electrical science and industry in the period since the first number was published in 1874; and we felt that at so memorable a milestone on the road of progress we might fairly take the advice once given by a famous statesman after a noteworthy achievement, and 'rest and be thankful.' But we are called upon this week once more to meet larger demands, and, rising to the occasion, we now put forth a number containing no fewer than 96 pages, or a gain of 24 pages over the previous record of a single week before. We cannot but call attention to a stride so tremendous. There is no need for us to enlarge upon it, or to emphasize its importance as evidence of the enterprise of electrical journalism in America, and the vast extent attained by the department represented in the arts and sciences. The number speaks for itself, from the first line to the last, and, big as it is, we know that every page will be turned and read with interest." Notwithstanding the fact that a full report of the Electric Light Convention was given, the current electric news was not neglected.

—The *Forum* for March contains the first of a series of essays on the fine arts. It is by Charles Elliot Norton, and is an attempt to give a definition of the fine arts,—a task of no small difficulty. The author thinks they may be defined as "the arts of expression in forms of beauty created by the imagination," and supports this view by an able discussion. He holds that these arts are "the only real test of the spiritual qualities of a race;" and he has some very uncomplimentary but, we fear, very true remarks about the deficiencies in this respect of the American race. Another article in the *Forum* which at first attracts attention is that by Cardinal Manning on "The Bible in the Public Schools;" but the article itself is disappointing. It is little more than a tirade against the public schools themselves as being irreligious; and, as for the reading of the Bible in the public schools of this country, he opposes it, though he is glad it is read in the schools of England. Mr. St. George Mivart has an article on "Darwin's Brilliant Fallacy," in which he reiterates his well-known views in opposition to the theory of "accidental variations," holding that a new species arises from "pre-ordained, definite variations due to the spontaneous reaction of the innermost nature of an organism." The article contains nothing particularly new, but in another paper the author promises to consider the subject of human reason, and to show that its origin is not explainable by Darwinism. Besides these papers, the *Forum* has one by Miss Kate Stephens on "Advanced Education for Women," showing the rapid progress that such education is making; another by Dr. Bacon, advocating the delivery of letters by carriers from every post-office in the Union; and other articles on various topics, which we have not space to particularize.

—Roberts Brothers will soon publish a new edition of "A Modern Mephistopheles," which first appeared in the No Name Series. The author's name, Louisa M. Alcott, is now printed on the title-page for the first time. It was one of the famous No Names, the authorship of which was never guessed by any one. The story resembled Hawthorne's style so much, that at its publication many attributed it to him. Appended to the volume is another story called "A Whisper in the Dark,"—a story written many years ago, but which never appeared in book-form.

—The *Revue Scientifique* proposes to open its columns to a symposium of facts relating to heredity in man. Its object is to collect reliable instances of unusual cases of heredity, and to subject the material thus gathered to a rigid analysis, in the hope of

shedding new light on this most important topic. The editor of the *Revue*, M. Ch. Richet, the well-known physiologist and psychologist, requests that all who have facts to present will send them to him. His address is 111 Boulevard Saint-Germain, Paris, France.

—Harper & Brothers have just ready "The Correspondence of John Lothrop Motley," edited by George William Curtis. Mr. Motley's daughters have collected these letters, chiefly addressed to the writer's family and to Oliver Wendell Holmes. They contain the autobiography of one of the most striking figures in American literary history. The author of "The Rise of the Dutch Republic," "History of the United Netherlands," and "The Life and Death of John of Barneveld," studied the history of liberty in an essentially American spirit. Wendell Phillips was his school chum, Bismarck his fellow-student at Göttingen; and as United States minister to London, Holland, and Austria, he made personal friends of all the literary and political celebrities of his day. Few lives have been so full of incident of universal interest. The work is in two volumes, and has a portrait.

—The Leonard Scott Publication Company (New York, 29 Park Row) has reprinted the famous Bismarck Dynasty article from the *Contemporary Review* for February (price 15 cents), a large special edition of that number having been exhausted on the day of publication. The authorship of the article continues to be the theme of much speculation in England. The Empress Frederick has thought it necessary to disclaim it, and so has Sir Morell Mackenzie. Many of those who claim to know, attribute it to Mr. Stead, the editor of the *Pall Mall Gazette*. Mr. Labouchere says he almost knows it was Mr. Stead, and sundry characteristics can be pointed out which lend color to this view. In the mean time eight editions of the *Review* have been called for in England.

—A novel feature in magazine literature was introduced in the *Nineteenth Century* for February. The editor has invited a number of his friends to send him from time to time, in the shape of letters to himself, remarks upon any books which in the ordinary and natural course of their reading may strike them as being worth special attention. He has suggested to them, that, whenever a book is thus met with, a letter about it should be written to him, giving the same advice as to a friend, and in much the same sort of easy fashion. He hopes in this way to obtain fresher and more spontaneous criticism than can possibly be always produced under the prevailing system of "noticing" books "sent for review." The first instalment of this series consists of a notice of Margaret Lee's novel "Divorce," by Mr. Gladstone; of the "Lyrics," and "A Village Tragedy" by Margaret Woods, by Frederick Harrison; Dean Burgon's "Lives of Twelve Good Men," by P. E. Prothero; Sir George Young's "Sophocles," in English, by W. S. Lilly; "Notes of Conversations with the Duke of Wellington," by Augustine Birrell; Miss Rives's "The Quick or the Dead?" and "Virginia of Virginia," by Hamilton Aide; M. Jusserand's "Wayfaring Life," by the Rev. Dr. Jessop; and George Pellew's "In Castle and Cabin," by John Morley.

—The New England Publishing Company have just published "One Hundred Lessons in Composition," by W. H. Huston of Toronto, which contains 400 practical exercises in composition, and is the sixth volume in their library of Teachers' Help Manuals. It will shortly be followed by "Manual of Rhymes, Selections, and Phrases," by Oscar Fay Adams; "Forty Friday Afternoons," by forty prominent masters, each giving what he considered his best exercises for a Friday afternoon; and "Common-Sense Exercises in Geography," a book of exercises—not questions—adapted to all grades and to the best American text-books. They have also just ready "School Music," by W. S. Tilden, of the State Normal School, Framingham, Mass., a series of papers from the *American Teacher*.

—The *Critic* observed the seventieth anniversary of the birth of Mr. Lowell, which occurred on Feb. 22, by printing seventy letters and poems from American and English men and women of letters, among whom are Tennyson, Whittier, Gladstone, Holmes, and Stedman.

—Mrs. Frank Leslie has sold to W. J. Arkell, of *Judge*, her *Frank Leslie's Illustrated Newspaper*, both English and German,

the transfers to be made May 1. Mrs. Leslie will retain and personally direct her other publications.

—Emin Pacha forms the subject of a paper by Elbridge S. Brooks in the February *Wide Awake*.

LETTERS TO THE EDITOR.

*.*Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith.
The editor will be glad to publish any queries consonant with the character of the journal.

The Soaring of Birds

MAY I ask space for a few comments on Professor W. H. Pickering's letter on the above subject, in *Science* of Feb. 22?

Professor Pickering holds that a bird which is moving with motionless wings in a horizontal wind is acted upon by three forces: (1) its weight; (2) a force "due to the excess of the velocity of the wind over the velocity of the bird," by which, since it is represented as horizontal and to leeward in his diagram, I suppose he means the friction between bird and wind; and (3) a force "due to the resistance of the air acting on the wings of the bird," which I take to mean the force derived from the impact of the air particles on the wings. This third force he assumes to have a direction opposite to that of the resultant of forces (1) and (2), and therefore to have one component vertically upward, and another to windward. This assumption seems to me to be erroneous. The horizontal component of such a force must surely be to leeward, as was pointed out by Hubert Airy in *Nature*, xxvii. p. 336; and the inaccuracy of this fundamental assumption of Professor Pickering would seem to invalidate his whole argument.

But let us follow it further. Force (3), he says, depends on the velocities of bird and wind, and he assumes first that these velocities are such that it is equal to the resultant of forces (1) and (2). In that case he says the forces acting on the bird will be in equilibrium. They would be, certainly, if the above assumption were true. "The bird," he then says, "will therefore continue to revolve about its mean position." How can a body which is in equilibrium revolve about a mean position? It must surely move with a uniform velocity in a straight line. He says again, "While these forces are in equilibrium, the bird is slowly drifting in the same direction as the wind." Why so? If the bird is in equilibrium, he must have the same velocity as he had at the instant at which he came to be in equilibrium, and that may or may not have had the same direction as the wind. In fact, if it is true, as Professor Pickering assumes, that the forces acting on the bird can be in equilibrium, the bird can move to any distance, in any direction whatever, with motionless wings. He has but to get up a velocity in the desired direction by using his wings, and then to poise his wings so that the forces acting on him may be in equilibrium. Since this result is contrary to experience, it makes the possibility of the bird's being in equilibrium under the given conditions doubtful; and it is obvious, that if force (3) has a leeward component, as I hold it must, its being equal to the resultant of (1) and (2) does not involve the vanishing of the resultant of all three; indeed, that whatever assumption may be made as to the magnitude of (3), the resultant of (1), (2), and (3) cannot possibly be zero.

Finally, Professor Pickering assumes the velocities of wind and bird to be such as to make force (3) greater than the resultant of (1) and (2). In that case, if the assumption criticised above were correct, the bird would be acted upon by a resultant force directed upwards and to windward, as Professor Pickering states. But if force (3) is directed upwards and to leeward, it will be obvious that the resultant force on the bird will be necessarily directed to leeward, and will not necessarily be directed upwards; and it follows, that, even if the velocities of wind and bird be assumed to be such that force (3) is greater than the resultant of (1) and (2), the bird's path will not necessarily have a general upward direction.

J. G. MACGREGOR.

Dalhousie College, Halifax, N.S., Feb. 27.

A New Departure in Effigy Mounds.

It was first asserted by Dr. J. M. De Hart that there are to be found exceptions to the ordinary rule followed by the mound-builders in the outlines of their quadruped animals; i.e., that in-

stead of portraying them with legs in range of the eye, so that only two are visible, there are cases in which all four legs are shown. This statement occurred in an article written by him on the mound-builders of Wisconsin, which appeared in the "Proceedings of the Wisconsin Academy of Sciences for 1876-77;" and he furnished illustrations of two such animals which he found on the northern shore of Lake, or Fourth Lake, opposite Madison. One of them he considered to represent a deer with divided horns: the other he called a bear.

Now, this report of his did not go uncontradicted; for it was maintained some years later by a writer in the *American Antiquarian* (vi. p. 13), that "there is in the mound no such divisions in the legs or horns," and the doubt is also expressed "whether any effigy intended to represent a deer ever had the horns separate, as this has." Dr. De Hart does not seem to have written in defence of his position, and no one hitherto seems to have taken up the cudgels in his behalf. For my part, until last year, I shared equally in the doubts of the second writer, because, in addition to scrutinizing all the drawings of effigies by Mr. Lapham and others contained in the "Antiquities of Wisconsin," together with a few subsequent incidental surveys of similar figures, I had personally examined some hundreds of original effigies in the field, without being able to find a case of divided legs.

When visiting the Four Lake country last summer, I did not fail to search for, and find, the two effigies delineated by the doctor, which are on the grounds of the insane-asylum. The result of the examination did not entirely confirm his statement; for, though the "deer's" legs are most decidedly apart, there is no division of the horns into antlers that I could discern. The following descriptions,

subdivision. There are several other effigies and a number of round mounds and embankments belonging to this group, but they are being gradually defaced and worn away by the patients passing back and forth over them in their daily walks.

On the same occasion I also found another four-legged animal (No. 2) not hitherto mentioned by any one. It is on the north side of Lake Wingra, nearly five miles distant as the crow flies, in a southerly direction from the one first described. The length of this effigy from the extremity of the muzzle to the rump is 127 feet, its body is 3 feet in height, and the legs are bent as if in motion. Last August, when I made the survey, it was in a fine state of preservation, the base outline being well defined. It is located on a knoll about twenty feet above the lake, less than one hundred feet from the shore; and on a high ridge above and to the east of it there are numerous round mounds, embankments, and effigies.

Leaving the vicinity of Madison, a north-westerly course in an air line of about 117 miles by the map brings us to a place where there is another effigy belonging to the same class (No. 3). It is located on the farm of Mr. George Gale on the N $\frac{1}{2}$ of section 10, township 18, range 8, on the west side of Black River, in Trempealeau County, Wis., within seven miles of the Mississippi River to the south-west. Its length from the muzzle to the tip of the tail, in an air line, is 234 feet, and the body is 2.5 feet in height. In this case, also, the horns, if such they be, are divided. The fore-legs are bent forward, and the hind-legs backward, which is probably intended to convey the idea that the animal is in motion. The tail is 144 feet in length, being just one and a half times that of the body and head combined. In addition to this one, there are four other effigies and several round mounds and embankments belonging to the same group, all of which were in a fine state of preservation last November, when my survey was made.

While these three examples, representing probably very different animals, are entirely unlike each other generally, they are yet fully sufficient to establish a class of four-legged ones; and probably by continued research others could be found in the same regions.

It may be further noted, in connection with these earthen effigies, that occasionally carvings or etchings are found on the sides of rocks and caves in Trempealeau and adjoining counties, which represent a great variety of figures of various kinds, and that among them are found some animals with two and others with four legs. The more interesting specimens of work have been copied by me. Although they may have been carved by another race, yet the fact still remains that both the artists in earth and the artists in stone adopted the same plan of outlines, but among the carvings there is by far the largest proportion of four-legged animals.

Whether this departure from a supposed rule be symptomatic of any incipient æsthetic evolution or not, and whether such construction of figures with legs apart preceded, was contemporaneous with, or succeeded, the similarly shaped carvings on the rocks, are questions which must be left to the future to answer.

T. H. LEWIS.

St. Paul, Minn., Feb. 27.

Queries.

42. LOOKING TO THE LEFT. — A writer in a recent number of the *Albany Argus* asks, "Why do theatre-goers prefer seats on the right of the house?" and suggests that when we are on the street we pass persons to the right and look to the left; that twenty-five or thirty years of this sort of thing naturally gets one accustomed to it; and, finally, that if one were to sit for two hours and a half or three hours in one position, if he has to keep his eyes to the right, he will find that it tires the muscles of the eyes quite perceptibly. Is there any evidence that this explanation is well founded?

43. DIGESTION OF FOWLS. — Permit me to ask a few questions about the digestion of fowls. Do they pick up the little stones when chicks, that serve through life, or do they secrete an acid that gradually digests even the pebbles, or have they a normal condition which produces the gravel in their gizzards as it is required for digestion?

S. E. W.

with outline diagrams plotted from my surveys, are now submitted to the archaeological world to substantiate the position taken.

The deer, so called (No. 1), is situated to the right of the road running from the asylum to the lake, and about equidistant from each. Its greatest length from the muzzle to the end of the tail is 108.5 feet, and the body is 1.5 feet high. Its horns or ears, whichever they may be, are divided into two sections, but there is no

GUARANTY INVESTMENT COMPANY

CAPITAL \$250,000.

Hon. ALBERT H. HORTON (Chief Justice, Kansas Supreme Court), Topeka, Kan., Pres't.

7% Guaranteed Farm Mortgages 7%

The Company calls the special attention of Investors to the following points :

- I. All loans guaranteed and interest payable semi-annually at the Importers' & Traders' National Bank, New York.
- II. Unusual fulness of information, not only about the security itself, but about the general development of the section where the farm is located.
- III. An examination each year of the general business of the Company and the Mortgages themselves by a COMMITTEE OF INVESTORS sent for the purpose.
- IV. Many hundred Mortgages taken and NOT A SINGLE FORECLOSURE.
- V. Exhibitions in New York at frequent intervals, of Kansas and Nebraska Farm Products. The Exhibition at the American Institute in the fall of 1888, received the *HIGHEST AWARD* of superiority.
- VI. Monthly Bulletins giving full information about all Mortgages offered for sale.

Address for Monthly Bulletin and Investors' Committee Report for 1888,

HENRY A. RILEY, General Eastern Manager, 191 Broadway, N.Y.

The Travelers of Hartford,

PAID POLICY-HOLDERS

\$200,000 in January, 1889, Alone.

This enormous mass of claim payments—by far the greatest ever made by THE TRAVELERS in a similar period since its organization—came out of the Company's treasury in *one month*; a rate which if maintained would carry its payments for the year up to \$2,400,000. Any other company of the sort in the country would have been totally swamped by it. THE TRAVELERS' beneficiaries did not have to wait action and payment one day.

Assets, \$10,383,000. Surplus, \$2,041,000.

THE CHEQUE BANK LIMITED.

ESTABLISHED IN LONDON, 1873.

CHIEF OFFICE, 4 Waterloo Place, Pall Mall, London.

TRUSTEES:

The Right Honorable JOHN BRIGHT, M.P.
The Right Honorable EARL BEAUCAMP.
Bankers: Bank of England.

The Capital of the Bank and its Guarantee Fund of 500 is invested in Government Securities.
The Bank does not discount Notes or Bills, nor speculate, but loans its Deposits against Government Securities, thus making the Cheque Bank Cheques EQUAL TO CASH—as Bank of England Notes are.

The Cheque Bank issues Cheques singly or in books from ONE POUND upwards, for the use of Travellers, and for others remitting money to Europe, available in every town in England, Scotland, Ireland, and Wales. In every town of Europe, and all other parts of the world, Cheque Bank Cheques are accepted as Cash by all the British Government Offices.

VISITORS TO THE PARIS EXHIBITION this summer can get the Cheque Bank Cheques cashed at 50 Banking Houses in Paris.
Travellers and those holding Cheque Bank Cheques can have their mail matter addressed to them, care of the Cheque Bank, London, who will take charge of the same and forward it to any address.

For Hand-Book containing List of upwards of 2000 of the principal Banking Houses throughout the World who Cash the Cheque Bank Cheques, and for all information, apply to the AGENCY,

CHEQUE BANK, Limited,

UNITED BANK BUILDING,
2 Wall St., New York.

A Novel by the Author of 'The Story of Margaret Kent.'

A DAUGHTER OF EVE.

1 vol., 12mo, \$1.50.

"Exceptional cleverness, effective satire, a great deal of humor."—Boston Advertiser.

"A story that for rare merit and interest will surpass even either of this author's former novels that have won such a place in the literary world."—Home Journal.

"Graciously winning as was 'The Story of Margaret Kent,' brilliant and moving as was the tale of 'Queen Money,' we are strongly inclined to say, after reading 'A Daughter of Eve,' that the author has attained to a still more gratifying artistic triumph than in the case of either of the other two novels we have mentioned. Brilliant sparkle and wit 'A Daughter of Eve' has in abundance, but it also has a definite ethical motive treated with inimitable taste."—Beacon.

STEADFAST.

By ROSE TERRY COOKE. 1 vol. 12mo. \$1.50.

"A tale of far more than ordinary worth. Intensely interesting."—Boston Gazette.

"Will interest those who are attracted by 'Robert Elsmere' and 'John Ward.' It is rare pleasure to read the story for its style alone, if for nothing more."—Conrad.

"Mrs. Cooke's knowledge of Yankee dialect is unsurpassed, and the conversations are often inimitably humorous."—Springfield Republican.

GREAT CAPTAINS.

By COL. THEODORE AYRAULT DODGE, U.S.A. 8vo.

With 21 maps. \$2.00.

"We are apt to think that books dealing with the details of warfare are dry. Colonel Dodge, however, is anything but dry. He makes the course of a campaign as fascinating as a romance."—The Beacon.

"ALEXANDER, HANNIBAL, CÆSAR, GUSTAVUS ALOLPHUS, FREDERICK, NAPOLEON, and the record of their achievements."—Boston Post.

Sold everywhere. Sent, postpaid, on receipt of price by the Publishers,

What Scott's Emulsion Has Done!

Over 25 Pounds Gain in Ten Weeks.
Experience of a Prominent Citizen.

THE CALIFORNIA SOCIETY FOR THE
SUPPRESSION OF VICE.
SAN FRANCISCO, July 7th, 1886.

I took a severe cold upon
my chest and lungs and did
not give it proper attention;
it developed into bronchitis,
and in the fall of the same
year I was threatened with
consumption. Physicians or-
dered me to a more congeni-
al climate, and I came to San
Francisco. Soon after my
arrival I commenced taking
Scott's Emulsion of Cod Liver
Oil with Hypophosphites regu-
larly three times a day. In
ten weeks my avoirdupois
went from 155 to 180 pounds
and over; the cough mean-
time ceased. C. R. BENNETT.

SOLD BY ALL DRUGGISTS.

\$3.50 PER YEAR, IN ADVANCE.

JOHN ERICSSON.

CAPT. JOHN ERICSSON died in New York at twenty-one minutes before one, Friday morning, March 8. He was cared for in his last moments by his attending physician, Dr. Joshua C. Boulee; his superintending engineer, V. F. Lassoë; and his secretary, S. W. Taylor. His last words were, "Give me rest," which followed an inquiry if he must die. Up to the last he retained his wonderful mental energy, his mind being concentrated on the work he had in hand.

The world has lost in this death one of its hardest workers, and one who has done his full share in advancing human welfare. So earnestly was he a worker, that he had not for years allowed any one to see him except on matters pertaining to his experiments. He would receive a tinsmith bringing a can for his laboratory; but he declined to meet Gen. McClellan, who expressed a wish to call on the great engineer. Even his associates could not induce him to break, in any case, this rule that he had made for his life.

His whole life was given to his work, and his only desire in living was to complete a task that he had set himself. For this reason he retained his residence

by the gloomy walls of the freight-depot of the New York Central Railroad. Its form, however, is the same as when Beach Street was one of the most aristocratic neighborhoods in the city.

His workshop was in the basement of his residence, and the whole building bore evidence of his vocation. The only ornaments in his parlor were models of his inventions, and a set of engraved resolutions passed by the New York Legislature in acknowledgment of his public services.

The first symptoms of the final illness appeared about three weeks ago, and, on account of his age, little hope was entertained from the first. But even on his death-bed his work was the one thing constantly before him; and among the last things he did was to leave special instructions to Mr. Lassoë, his assistant, for the completion of the work he was engaged in, the development of his sun-motor. He also left to Mr. Lassoë certain plans which he had originated for American coast defences.

Capt. Ericsson was born July 31, 1803, in the province of Wermland, Sweden. His father, Olof Ericsson, was proprietor of mines; his mother, Sophie, the daughter of an iron-master.

He was married in England about fifty years ago, but his wife has been dead a quarter of a century; and he leaves no children.

JOHN ERICSSON.

THE "MONITOR" OF 1862.

in Beach Street so long after the locality had been encroached upon by business structures and tenement-houses. This residence originally faced on St. John's Park, but is now shadowed

His special talent showed itself at the age of ten, when he constructed a miniature saw-mill and a pumping-machine that attracted notice. At twelve he was made a cadet of mechanical en-

gineers; the following year, a leveller on the canal. At seventeen, Ericsson entered the army as an ensign, and rapidly reached a lieutenantcy in consequence of his beautiful military maps, which had attracted the special attention of King Charles John (Bernadotte).

steam-engine, and a famous system of artificial draught for steam-boilers, dispensing with huge smoke-stacks, and economizing fuel. To the steamship "Victory," in 1828, he applied the principle of condensing steam and returning the water to the boiler; and four years later he gave to the "Corsair" the centrifugal fan-blowers

IRONCLAD CUPOLA VESSEL DESIGNED BY JOHN ERICSSON, 1854.

When about twenty-two years old, Lieut. Ericsson constructed a flame-engine of 10 horse-power, and journeyed to London in 1826, on leave, to introduce it. Once there, he resigned his commission. The resignation was accepted, but first he was promoted to a captaincy. He has never returned to his native country, but from it has received many honors and decorations; while in 1867 a great granite monument, quarried by the unpaid labor of the miners,

now generally used in American steam-vessels. In 1830 he introduced in the locomotives "King William" and "Adelaide" the link motion for reversing steam-engines. In 1834 he superheated steam in an engine on the Regent's Canal Basin.

In 1829 the Liverpool and Manchester Railway had offered a prize for competing locomotives. Ericsson planned and hurried to completion an engine, the "Novelty," in seven weeks. The London

STEAM FIRE-ENGINE DESIGNED BY JOHN ERICSSON, 1841.

some of whom had worked for his father, was set up with gala festivities in front of his mansion, inscribed, "John Ericsson was born here in 1803." It is under this stone that his last resting-place may be, though at this writing nothing definite can be said.

During the next few years, Ericsson produced about forty machines. They included a file-cutting device, an instrument for taking soundings (still in use), a hydrostatic weighing-machine, an apparatus for making salt from brine, a pumping-engine, a rotary

Times of Oct. 8, 1829, said that in speed it "far excelled" all competitors. It shot along the line at the amazing rate of thirty miles an hour; but Stephenson's "Rocket" proved superior in point of traction. Ericsson in 1829, nearly threescore years ago, constructed a steam fire-engine, employed in putting out a fire in the Argyle Rooms, which was objected to as throwing too much water.

So much for his progress in England. For Ericsson's removal to

America in 1839, we have to thank the English Admiralty. In 1837 he built a tug, having two propellers of $5\frac{1}{2}$ feet diameter, invited the British Admiralty to inspect it, and towed their barge at a rapid rate; but their lordships solemnly concluded, that, as the motive-power was in the stern, the novel craft would not steer. Thus it was in America, in 1841, that he began to build the "Princeton," the first naval vessel that ever carried her machinery under the water-line, out of the reach of hostile shot.

ERICSSON'S CALORIC ENGINE FOR DOMESTIC PURPOSES.

In 1839 Congress had authorized the construction of three war-ships. In 1840 the secretary of the navy, in obedience to that law, ordered two to be constructed. The question of whether steam could or could not be successfully applied to war-vessels had not then been solved, the fear of danger from ignition by fire prevailing in the minds of all naval men. One of the officers of our navy, Capt. William Hunter, submitted a plan by which wheels were to be inserted in the bilge of the vessel on each side,—submerged wheels. Ericsson had demonstrated his plan to be feasible, in his experiments in England. The secretary of the navy, in authorizing the construction of these two vessels, directed that one was to be built on Ericsson's plan, and one on Hunter's plan. Hunter's plan proved a total failure: Ericsson's plan laid the foundation of the present steam marine. The "Princeton" was the first war-propeller ever built on the face of the earth, and in her he brought forward not only his propeller, but a great many appliances appurtenant to steam navigation which have since been used in our service.

The honor of having built the first practical screw-steamer was thus Ericsson's,—an invention which was matched by that of the "Monitor," fifteen or twenty years later.

Such a device was offered by Ericsson in 1854 to Napoleon III. The story of what happened in 1862 is too well known to need repetition here. By extraordinary energy and executive skill, the "Monitor" was launched, with steam-machinery complete, a hundred days from the laying of the keel plate, and arrived in Hampton Roads just in time to defeat, March 9, 1862, the Confederate ironclad "Merrimac," which had destroyed the "Cumberland" and "Congress," and was about to sink or disperse the rest of the government's wooden fleet. Naval warfare was revolutionized.

The Mechanics' Institute of New York offered its great gold medal in January, 1840, as a prize for the best plan of a steam fire-engine. Ericsson, having several years previously designed such machines in England, among which may be mentioned the steam fire-engine employed during the memorable fire at the Argyle Rooms in London in 1830 (the first time fire had ever been extinguished by the mechanical power called forth by fire), had no difficulty in producing plans complying with the conditions of the Mechanics' Institute in a manner warranting the award of the prize offered.

His caloric engine was produced in 1833. In 1853, a voyage of the caloric ship "Ericsson," a vessel of 2,000 tons, 260 feet long, from New York to Washington and back, showed, that, though economical in fuel, the new heated-air motor could not produce speed enough at sea for commercial purposes, nor compete on any large scale with steam. Still, it has been applied successfully in thousands of engines to minor useful purposes.

Favored by the possession of a robust constitution and ample means, Ericsson devoted many of his last years exclusively to the investigation of solar heat, and to the determination of the mechanical energy which the sun has in store for mankind when the coal-fields become exhausted. A sun-motor (illustrated in *Nature*, xxix. p. 217) erected in 1883 was found to develop under ordinary sunshine a steady and reliable power. Although he was eighty-six years old, and by no means well since the beginning of the year, Capt. Ericsson continued to labor at this motor until within two weeks of his death; and, as he saw his end approaching, he expressed regret only because he could not live to give this invention to the world in completed form. It occupied his thoughts up to his last hour. While he could hardly speak above a whisper, he drew his chief engineer's face close to his own, gave him final instructions for continuing the work on the machine, and exacted a promise that the work should go on.

No visitor was allowed to enter his workshop. Even his most intimate friends have never gained entrance there. Nor has any servant been in the room where the captain spent more than twelve hours daily for thirty years.

Here in his workshop, as it were, Ericsson lived, and here he died, a recognized leader among those who have added to human welfare, and honoring by his name the rolls of more than a score of associations of learned men.

THE DENIO FIRE-ALARM.

WE illustrate herewith a simple automatic fire-alarm combined with an ordinary electric push-button, which is being manufactured by the Denio Fire Alarm Company of Rochester, N.Y. The construction and operation of the device will be readily understood from the following description. In a thimble with an internal flange at one end, an external hollowed flange at the other, is placed

DENIO'S FIRE-ALARM.

a spring slightly longer than the thimble. This spring, one end of which bears against the internal flange, is compressed, and held in place by a pin which passes through it, the head of the pin fitting snugly in the recess made in the external flange of the thimble. The pin is sufficiently long to project entirely through the orifice in the internal flange end of the thimble. When the parts have been put together, the pin is secured in place by soldering to the flange, the solder used for this purpose being an alloy which will fuse at a low temperature, 150° to 160° F.

By removing the porcelain knob from any of the ordinary push-buttons now in use, and substituting this thimble, the button is

converted into an automatic fire-alarm, without in any way interfering with its use as a call. Pressure upon the thimble causes electric contact between the springs in the base of the button-fixture, in the usual manner, completing the circuit and ringing the bell.

AN IMPROVED ELECTRIC SYSTEM.

THE Sperry system of electric lighting, which has been widely introduced, especially in the Western States, has recently been considerably improved. The dynamo as now made is shown in

FIG. 1.—SPERRY DYNAMO COMPLETE.

As a fire-alarm, it operates as follows: When the heat of any room in which this attachment has been placed reaches a predetermined temperature, the alloy melts, and releases the pin, which is forced out of the thimble by the expansion of the spring. The springs in the fixture are then brought into continuous contact by

Fig. 1. A special feature of this is the automatic regulator. The brushes consist of overlapping flat copper strips attached to a movable yoke. This yoke is connected by means of an electro-magnetic regulator placed in the lamp-circuit. Any variation in the electrical resistance of the lamp-circuit operates the

FIGS. 2 AND 3.—ARMATURE OF SPERRY DYNAMO.

the pressure of the pin, the circuit is thereby closed, and the alarm transmitted to a central station, where measures can immediately be adopted for extinguishing the fire. The device is applicable to open or closed circuit, and to all purposes for which a thermostat is required. It is an efficient substitute for the more complicated and expensive thermostats, and should be very reliable, as the wires and connections are constantly being tested.

keeper of the electro-magnet. By an ingenious device, this movement adjusts the current of the dynamo in proportion to any variation in the resistance of the lamp-circuit. The manufacturer claims that all of the lights, a single light, or any number from zero to full capacity, may be extinguished without danger to the dynamo, and without the presence or knowledge of the dynamo-tender or engineer.

The field-magnets (Fig. 4) are provided with an annular recess, in which the annular armature (Figs. 2 and 3) rotates. It is claimed that by employing this peculiar construction of the armature, and

FIG. 4. — FIELD-MAGNETS, SPERRY DYNAMO.

exposing its inner surface to the action of the inner pole-pieces, the output of electrical energy is increased.

Another feature of the Sperry armature is that there is no overlapping of coils, each coil being separate and distinct from the

FIG. 5. — SPERRY LIGHTNING-ARRESTER.

others. Thus any mechanical injury sustained by one coil will not cause the destruction of the whole armature, as the injured part can easily be removed, and replaced by a new one, without disturbing any other coil.

Each lamp is provided with a hand-switch, and also an auto-

matic switch, which cuts the lamp out of circuit in the event of neglect or carelessness on the part of the trimmer, or trouble in the lamp itself. The regulation is such that the carbon rod is made to operate in both directions, up and down, without friction. On starting the machine, the normal arc is at once secured, and maintained throughout the entire operation.

The discharge-plates of the lightning-arrester are movable, one from the other, in such a way as to break the arc established between these two plates, which follows the discharge of static electricity from the line, be it produced by lightning or friction electricity by belts, which has been discovered to be the case in some instances. The arc being ruptured automatically, and the plates restored, no

FIG. 6. — SPERRY ARC-LAMP, TOP REMOVED.

FIG. 7. — LAMP COMPLETE.

shutting-down of the light is necessary; and the consumer knows nothing of its operation, and is not annoyed by the extinguishing of his light. All possibility of disabling the dynamo from lightning is done away with, either from lightning direct or from the instantaneous short-circuiting of the dynamo, resulting from the arc established between the two leads by way of the two discharge-plates, which are present in all forms of lightning-arresters. These lightning-arresters have operated continuously for over two years upon sixty and eighty light circuits. Heavy discharges have been taken off of lines continuously all last summer and spring, and the apparatus has not been injured in the least. A single lightning-arrester serves for an entire circuit, being attached to both positive and negative wires between the dynamo and first lamps on either lead, the ground wire being attached to the rear terminal or binding-post, all of which are shown in Fig. 5.

GRAY'S TORSIONAL TESTING-MACHINE.

THE accompanying figure illustrates an apparatus recently designed by Professor Thomas Gray of the Rose Polytechnic Institute, Terre Haute, Ind., for the purpose of testing the torsional rigidity of different kinds of materials.

The figure has been prepared from a photograph of a rough and

GRAY'S TORSIONAL TESTING-MACHINE.

inexpensive form of the machine, which was somewhat hurriedly made in the workshops of the institute by students, for use in the engineering laboratory course of the current year.

The apparatus, as here shown, consists of a wooden trestle, on the top bar, *D*, of which there is mounted a cross-beam *A*, about four feet in length, which rests, through knife-edges at its centre, on a support which can be clamped at any point of the bar *D*. The ends of this beam are cut to circles having the knife-edges as centre; and to one end a thin steel trap, *C*, is fixed, the lower end of which is attached to a cross-beam, *F*, of the same length as *A*. The beam *F* is clamped to one end of the specimen, *G*, which is being tested by means of strong clamps, which take different forms, and are made of different materials, according to the form and nature of the specimen. The other end is held in a similar clamp at *H*, and this clamp is firmly fixed to the trestle.

The end of the specimen to which the beam *F* is attached is kept in position by means of an attachment similar to the tail-stock of a lathe, the clamping-screw for which is shown at *I*.

This centre-bearing also prevents any cross-bending force being applied to the specimen by the weight of *F*. The torque, or twisting-couple, is applied to the specimen by hanging weights, *K*, *K'*, on the free ends of the beams *A* and *F*. These weights should be of equal amount, as they then produce a pure twisting-couple without applying any force to the centre-bearing.

The amount of distortion produced by any torque applied to the specimen is measured by means of two indices *E*, *E'*, which are clamped to the specimen at a measured distance apart. The outer ends of these indices carry a graduated arc, on which the angular displacement can be read by means of a fixed mark or vernier. For specimens of such large diameter that the limit of elasticity is exceeded before a sufficiently large deflection can be given to the indices *E*, *E'* to render this method sensitive enough, the deflection is indicated by a multiplying index, *B*. An important feature of this apparatus is the elimination of any uncertainty as to effect of

the clamps by measuring the relative twist at two sections a short distance from the ends.

This same method was adopted some years ago by Professor Gray, in a series of experiments on the elastic constants of rocks, but the apparatus was not then made in a permanent form. A considerable extension of the experiments is now contemplated in connection with investigations in seismology, under the direction of Professor Mendenhall, in which it is intended to determine the elastic constants of a number of rocks, for the purpose of ascertaining the theoretical velocity of a seismic wave.

In the more complete design of the testing-machine above described, both ends of the beam *A* are connected by straps or links to the beam *F*. The tail-stock centre-bearing is then omitted, and cross-bending stresses are avoided by mounting the clamp *H* on gimbals, which allow freedom to transverse motion. A graduated disk is then substituted for one of the indices *E*, *E'*; and the other index is carried on a bar which extends from the clamp, in a direction parallel to the axis of the specimen, up to the front of the graduated disk. The relative distortion is thus read off direct when that method is sufficiently sensitive, or by means of a second index attached to the disk when higher sensibility is desirable. For some purposes the gimbals are mounted on a worm-wheel, which turns round an axis parallel to the direction of the specimen, which thus allows an unlimited amount of twist to be given to the specimen. This becomes necessary when torsional strength is the object of investigation.

With the apparatus here illustrated, specimens of any length up to three feet can be included between the clamps; while specimens of any length can be tested in sections of three feet or less, the ends being simply allowed to project beyond the clamps, and the tail-stock bearing modified to a V instead of a centre-bearing. As regards the power of this machine, it is capable of testing a three-inch steel shaft up to its limit of elasticity.

THE MACRÆON SECONDARY BATTERY.

THERE is no field in which experiment is being more actively prosecuted than in that of the storage of electrical energy. From the experience which has been gained in the last five or six years, the failings of secondary batteries have become pretty well under-

FIG. 1.—THE MACRÆON STORAGE-BATTERY.

stood, and many inventors are trying to remedy them. The two types of battery which have been at all generally used are the Faure and the Planté. In the former a support-plate is provided, and some salt of lead is mechanically applied to it, which forms the active material. In the latter the active material is obtained from the support-plate by reversing the current passing between two lead plates in dilute sulphuric acid. The Faure cells take but a very short time to manufacture: the Planté type takes several

months. The advantages of the Faure type are the ease of manufacture, and the capacity, which is greater than that of the Planté type. The disadvantages are in the rapid depreciation and the limited discharge-rate.

In the Macraëon battery the attempt is made to take advantage of the good points, avoiding the troubles. This is done in the following way. The negative plate is made according to the Faure process, as distinguished from the Planté. A framework of lead is filled in with active material obtained by fusion. The cross-bars making up the frame are thinner than the finished plate, so nothing but the active material is exposed to the liquid. The negative plates are permanently connected to the metallic box, which takes the place of the glass or rubber boxes now generally used.

The positive plates are made according to the Planté plan; the active material is obtained from the support itself by the chemical action of the current. But instead of the forming process taking months to accomplish, as in the original Planté process, it is accomplished in a few hours, the result of the special electrolyte used in the Macraëon battery. The form of the positive plate is also an important question. In this cell it is made of corrugated strips of

ELECTRICAL NEWS.

The Velocity of Light.

ACCORDING to the electro-magnetic theory of light, which recent investigations, mathematical and physical, have rendered so probable, the velocity of light is equal to the quantity v , the ratio of the electro-static and electro-magnetic units of electro-motive force. Sir William Thomson has been engaged for some time on a series of measuring-instruments which will, by electro-static force, measure potentials from 40 to 50,000 volts. The method of calibration allows a determination of v to be made. The easiest way to get known potentials up to 200 or 300 volts is by sending a measured current through a known resistance, the difference of potential at the terminals of the latter being CR , the product of two easily measured quantities. This is the plan Sir William adopts for the calibration of instruments giving the lower readings, and the accuracy is within at least one-twentieth per cent. By the aid of condensers, these potentials are multiplied up to 2,000 or 3,000 with an accuracy of one-fifth per cent; and, by the aid of an intermediary electrometer, this is raised to 10,000 volts, with about the same limit of accuracy. This last measure, based on the original electro-magnetic determination with the resistance and current may now be compared with the electro-static measurement of the same potential made by an electro-static balance. Sir William has not been able to make sure of the accuracy of this last instrument to within more than one-half per cent, but within this limit the comparison of the two methods gives a ratio within one-half per cent of 300,000 kilometres per second. The velocity of light is known to be within one-fourth per cent of this value, — a most satisfactory agreement, speaking well for the accuracy of the new instruments.

The series of ammeters that Sir William lately developed will be of great practical benefit to electricians; their great range, accuracy, and permanence making them almost invaluable for certain classes of work. The series of volt-meters on which he is working will be of equal value, and we look forward to the time when they will have passed through the experimental stage.

ABSOLUTE RESISTANCE OF MERCURY. — In a recent number of *Wiedemann's Annalen*, F. Kohlrausch publishes a redetermination, which he has carried out with elaborate precautions, of the absolute resistance of mercury. The method employed was Weber's method of the damping of a magnet in a coil, with some slight modification of Dorn. The result arrived at is, that the resistance of a cubic centimetre of mercury at 0°C. is 94,060 centimetre seconds. In order to compare this with the B.A. unit, Mr. Glazebrook has compared one of the author's mercury standards with the B.A. unit in the Cavendish Laboratory, and finds, that, according to Kohlrausch's determination, one B.A. is equal to 0.9866 of an ohm. This would give a length of between 106.2 and 106.3 for the column of mercury of one square centimetre in section, having a resistance of one ohm.

ELECTRIC LOCOMOTIVES FOR MINES. — In this country the only applications of electricity to traction in mining, with which we are acquainted, is in Lykens, Penn. In this, current is conveyed to

FIG. 2. — THE MACRÆON STORAGE-BATTERY.

lead, fastened at the top to the crossbar of a lead frame, while at the bottom they have a freedom of movement which prevents "buckling" when the strips expand on discharge. These positive plates are fixed to the metallic top of the box. When the cover is in place, the top of the cell is positive, and the bottom is negative, with an insulation between them. The closing of the cell avoids the occurrence of acid fumes, and the evaporation of the acid.

The following tables give some data as to the performance of the cells: —

Stationary or "Central Station" Type.

Size.	Normal Charging Current.	Normal Discharge Current.	External Dimensions.			Weight Complete in Pounds.	Normal Capacity in Amperé Hours.
			Length.	Width.	Height.		
A	6	1-8	11	5¾	4½	35	50
B	12	1-17	11	5¾	6¾	52	100
C	20	1-32	10½	10	6½	80	200

the motors through an overhead wire. In Europe there are several successful examples of electric tramways in mines, and lately Messrs. Immisch & Co. have built a new mine-locomotive from the designs of Mr. Reckenzaun. Storage-cells are employed for supplying current, and a single motor of four-horse power. The gearing is peculiar. On the armature-spindle is a small phosphor-bronze pinion. This gears into four steel pinions placed in the same plane, and 90° distant from each other. These pinions are bushed with gun-metal, and run on steel pins carried on a cast-iron disk. The disk revolves on a journal turned outside of the end of the motor-bearing. Outside of, but in the same plane with, these pinions, is fixed an annular casting of gun-metal, with teeth cut on the inside. The steel pinions gear into the ring, which forms a fulcrum on which they revolve when the motor-spindle turns. The power is transmitted from the cast-iron disk by a sprocket-pinion keyed to it on the inside next to the motor, and a steel chain connects this sprocket-pinion to a suitable wheel mounted on one of the axles, while the other axle is connected to this by coupling-rods. The storage-battery consists of forty-four modified Tatham cells, each box being 10 inches by 6½ inches, by 11 inches high. The boxes are lead-lined, and arranged in sections of three in wooden trays. Each box contains nineteen plates 7 inches by 4½ inches, by ⅜ of an inch thick, and has a capacity of 150 ampère hours, the weight being 53 pounds. The rate of discharge varies from 25 to 50 ampères, and sometimes, on starting, this increases to 65 ampères. Taking 40 ampères as the average rate, the weight of these cells for a discharge equivalent to one horse-power is nearly 500 pounds, and per horse-power-hour storage-capacity, 134 pounds. The Messrs. Immisch are now working on some improvements by which the capacity will be increased. This locomotive, on a grade of 1 in 70, would just move, with a load of twenty loaded cars equivalent to eleven tons. With fifteen cars, weighing eight tons and a half, the speed was three miles per hour, the current being 45 ampères at 100 volts pressure. On a grade of 1 in 40 the maximum load was eight cars, and on 1 in 25 it was six cars, the speed being a little over two miles an hour. On the level the locomotive could draw thirty cars, the current employed being 45 ampères.

FELLING TREES BY ELECTRICITY.—Hitherto machines for felling trees have been driven by steam-power, but this is sometimes inconvenient, especially in thick woods; and now the *London Times* reports that electric power has recently been adopted in the Galician forests. Usually in such machines the trunk is sawed, but in this case it is drilled. When the wood is of a soft nature, the drill has a sweeping motion, and cuts into the trunk by means of cutting edges on its sides. The drill is actuated by an electric motor mounted on a carriage, which is brought up close to the tree and shackled to it. The motor is capable of turning round its vertical axis; and the drill is geared to it in such a manner that it can turn through an arc of a circle and make a sweeping cut into the trunk. The first cut made, the drill is advanced a few inches, and another section of the wood removed in the same way, until the trunk is half severed. It is then clamped to keep the cut from closing, and the operation continued until it would be unsafe to go on. The remainder is finished by a hand-saw or an axe. The current is conveyed to the motor by insulated leads brought through the forest from a generator placed in some convenient site.

HEALTH MATTERS.

Public Inspection of Food.

THE following resolutions were offered by Dr. George Strawbridge at a recent meeting of the Philadelphia County Medical Society:—

“The Philadelphia County Medical Society begs to call the earnest attention of city councils and the Legislature of Pennsylvania to the pressing need of provision for the inspection of all meat and milk used as food, with a view of furnishing sound meat and milk to the people.

“The society would also urge the necessity of killing and destroying all animals afflicted with tuberculosis, and the owner should be indemnified by the State.

“The society also recommends that a committee of five be appointed by the president of the society, whose duty it shall be to represent the society with a view of obtaining further information, and to confer with other bodies acting in this matter.”

Dr. Strawbridge, in introducing his resolutions, said: “Statistics as reliable as can be obtained make the statement not too broad, that in Philadelphia, about the present time, there is from three to three and one-half per cent of tuberculed meat used, and from six to eight per cent of tuberculed milk. Here in Philadelphia to-day there is no inspection of any kind. The best the board of health could do was to obtain an appropriation of fifteen hundred dollars for the appointment of a milk-inspector, who will probably start to the stations to see how much water goes into the milk. Anybody can dump any kind of food in Philadelphia, and we must take it; but if we refuse to eat it, we are told that we are not good citizens. Meat ought to be inspected when alive, and also during the process of slaughtering. Unless you can inspect the animal alive, and also when the internal parts can be viewed, the inspection is useless. In the inspection of milk, the principal thing is to see the cows that give it, so that they are not diseased, and to inspect it at its place of delivery.”

The resolutions were adopted, and a committee was appointed consisting of Drs. Leffman, Huidekoper, Shakespeare, Osler, and Cleeman.

CHOLERA CONTAGION IN DRINKING-WATER.—F. G. McKean, chief engineer in the United States Navy, states that during ten days in 1885, nine hundred persons died of cholera on the island of Takashima in Japan, and that the disease often appears on the island. Suspicion was drawn to the drinking-water, which was brought from the mainland. During 1888 the use of this water for drinking-purposes was abandoned, and distilled water was used instead. Although cholera prevailed on the neighboring islands, Takashima was entirely exempt. This exemption may have been but a coincidence; still, it is more than probable, from our knowledge of this disease, that the purity of the drinking-water is to be credited with the immunity which the population of the island enjoyed. To be absolutely certain of this, will, however, require more continued observation.

NOTES AND NEWS.

IN the “Sixth Biennial Report of the State Board of Agriculture of Kansas,” Mr. E. B. Cowgill, in the report on the sorghum-sugar industry, says: “The season of 1888 has been looked upon as the one which should settle the question as to the financial success of the sorghum-sugar industry, and, fortunately for the incoming industry, the answer must be taken as an affirmative one. It is true that not all of the factories in Kansas are able to show balances of profit. The fact, however, that the favorable results obtained in 1887 at Fort Scott have been more than repeated at that place in 1888; that a factory at Topeka has demonstrated the practicability of the sugar industry at that place; and the further fact that Conway Springs and Douglass, in the face of adverse circumstances, have shown the industry to be independent of all patented processes and machinery,—will go far toward assuring all diligent inquirers of the success of the Northern sugar industry. Indeed, upon the most careful study of the subject, I have no hesitation in saying that the sorghum-sugar industry is now on such a footing as to invite the investment of capital, where such investment is placed under good business management, efficient, practical skill, and competent, scientific direction.”

—A recent invention of Messrs. Randall & Carter, for the preservation of freestone from the effects of weather, was exhibited by them at the Cannon Street Hotel, London, on Feb. 15, in the presence of a large number of architects and builders. Several specimens of well-known oolitic freestones, which had been treated by this process in such a manner as to make their surfaces quite hard enough to be polished, were shown. The process consists of treating the stone with a compound of milk of lime, acetic acid, and cane-sugar (or molasses), which, when applied, soaks into it for a depth of about half an inch, and produces a slight chemical change, materially hardening it. The stone may either be entirely im-

mersed in this solution, or the latter may be applied to its surface with a brush. The surface is then rubbed to a face with fine grit, and allowed to dry, after which it is subjected to a diffused dry heat of from 130° to 160° F. in an oven. When the stone to be treated is fixed in position, as in a building, it is stated that the compound may be applied with a brush, either with or without heat subsequently. Although it is admitted that by heating the stone its durability is greatly increased, the *London Builder* thinks it questionable whether this is practicable on a large scale after it is built up. But even supposing it were practicable, it is very doubtful whether the hardened surface would protect the stone for any great length of time. Experience has shown, that, where only a hardened coating has been formed, moisture soaks in, either through the cracks in the masonry or through portions of the surface of the stone itself, rendered vulnerable by the defective application of the preparation, whatever it may consist of. The moisture collects behind the hard coating, and produces a line of weakness, in consequence of which the thin crust flakes off. Moreover, it is wrong to suppose, that, because a lime solution hardens a stone, the latter thoroughly resists decay, as has often been suggested. The mere fact of the stone being hardened does not add much to its durability from a chemical point of view, unless the hardening material be acid-resisting. The only effect of the hardening is to render the stone less absorbent, and therefore slightly more durable, for a few years at most.

— Lord Wolseley, who is not often caught tripping in making hasty statements, writes as follows in the current number of the *Fortnightly Review*: "The battles of the future will be very different from even those of 1870. . . . One remarkable change will be the absence of nearly all that terrific noise which the discharge of five or six hundred field-guns, and the roar of musketry, caused in all great battles. . . . The sound of cannon will be slight, and will no longer indicate to distant troops where their comrades are engaged, or the point to which they should consequently march. Our sentries and advanced posts can no longer alarm the main body upon the approach of the enemy by the discharge of their rifles. The camp or bivouac will no longer be disturbed at night by the spluttering fire of picquets in contact with the enemy. Different arrangements for giving the alarm upon the approach of hostile columns will have to be resorted to. The main column on the march cannot in future be warned, by the shots of flanking parties, of the enemy's proximity, and a battle might possibly be raging within a few miles of it without that fact becoming at once apparent." *Nature* asks that some competent member of the "Scientific Corps" will kindly explain.

— The prefect of police in Paris has issued a new set of regulations with regard to the fire brigade service in theatres, which will, it is thought, reduce very much the risk of fire; so far, at least, as it can be reduced in the many theatres in Paris which have always been, and must remain, from the position they occupy, regular death-traps. A certain number of firemen are allotted to each theatre, who, under no pretence, are to be called out of the theatre, or to receive visits from friends or acquaintances. The chief of the detachment has the responsibility of seeing that all the apparatus for extinguishing a fire is in its allotted place and in proper order, and the commissary of police is to satisfy himself that this has been done before the theatre opens. During the representation the chief of the detachment must be constantly moving about to see that the men are at their posts, that no one is smoking in the corridors or carrying open lights, and that access to the reservoirs and fire-plugs is not hampered by placing any scenery or stage properties in the way. He is to examine the manometer, and, if he finds that there is a deficiency of pressure in the water-mains, he must inform the nearest post of the fact. In the event of an insignificant outbreak, recourse is to be had only to the apparatus within reach of the *foyer*; but, if the outbreak is of a more serious character, the nearest post is to be informed by telegraph. At the close of each representation the firemen are to make a round of the theatre, and see that the iron curtain is lowered, the buckets filled, and the folding doors closed, and, in the event of these not working smoothly, they must be repaired at once. The manager of the theatre is required implicitly to obey the orders of the district com-

missary of police, who, in the event of an outbreak of fire, assumes the sole command of the theatre until the arrival of the prefect of police or the chief officer of the fire brigade.

— *Nature* makes the following extract from a letter addressed by Mr. A. W. Tuer to a contemporary: "The melodious hum of skating was perhaps never heard to greater advantage than through the crisp air of a bitterly cold morning little more than a fortnight ago,—the first Sunday in the year. Almost as soon as Kensington Gardens were entered, one became conscious of a clearly defined musical sound coming from the direction of the Round Pond,—G as nearly as I could judge, but corrected to G sharp, when, half an hour later, I got to a piano. I had wished to compare the notes—probably lower—given forth by other and larger sheets of ice, but procrastination strangled an opportunity which perhaps others will take when it again offers. Comparing a sheet of ice to a taut string, and the countless skates to the hairs of a bow,—scientifically, a poor comparison enough,—the sound might be expected to have been like that produced by the scraping of a fiddle, but it exactly resembled the whistle of a distant locomotive."

— The following description of some of the most important features of the subsurface torpedo-boat lately submitted to the Navy Department by the Columbian Iron Works of Baltimore, and the uses for which it is intended, serve to clear up several points which might possibly have caused a misunderstanding as to the nature of the craft. The boat is cigar-shaped, and is capable of being operated under three different conditions: first, above the surface, that is, with nearly half of it above water; second, awash, that is, with only a few inches of the back exposed, together with the conning tower; third, completely submerged, that is, with nothing whatever appearing above the surface. In the last condition, which is the primary condition for torpedo warfare, the boat's means of offence is a horizontal tube directly in its axis, from which are discharged 8-inch projectiles either by pneumatic power or by powder. These projectiles are capable of giving several hundred feet range, and the gun and projectile are constructed on a principle first propounded by Lieut.-Commander Barber at the United States torpedo-station in 1873, but separately invented, and proved successful by Mr. Holland, the inventor of this boat. In lieu of this submarine gun, the boat will be fitted with any kind of locomotive torpedo that the Navy Department may desire to be fired from this or a similar tube. In addition to this tube in the axis of the boat, there is another 8-inch tube, fitted at an angle, for over-water fire at distances of 1,000 yards or thereabout. It is intended to use this tube for throwing dynamite shells, under circumstances where the boat cannot approach the enemy within torpedo range, or where it may be preferable not to try to do so. The boat has a double skin on the upper forward part, separated by about a foot of space; and this space is filled with water, which flows freely into it. Aft of this, and forward of the gun-room, is a vertical bulkhead of several inches of iron. When, therefore, she is lying awash, and using her upper pneumatic gun (which makes no smoke), she will be almost invisible to the enemy, and, if struck by machine-gun projectiles, she is almost certain to be uninjured.

— The wine-making industry in California is the subject of an interesting article by Edwards Roberts in the supplement to *Harper's Weekly* of March 9. The article is copiously illustrated.

— The Eiffel Tower has already attained a height of 280 metres, and in a month it will be completed by the turret and the electric lantern, which will give it its greatest height of 300 metres. The Paris correspondent of the *London Builder* says, "It is curious to notice to-day how inferior is the effect produced by this enormous piece of iron-work to the idea that people had of it in advance. Seen from the environs of Paris, it overpowers the city, and appears immense by the side of the large monuments, which are reduced to very small dimensions; but the nearer one approaches it, the less is one aware of its colossal proportions, and the eye hardly sees what relation can exist between the thin termination of the tower and the gigantic arches of its base. There is an optical illusion about it which will always weaken its general effect, and disappoint the hopes of the promoters of this useless attempt to astonish the eye by its giddy height."

John Ericsson.	
PUBLIC HEALTH A PUBLIC DUTY..... 198	

JOHN ERICSSON was a man with the best of brain-power, with confidence in himself, who lived at a time when the world was ripe for what he could best do. He was essentially a great mechanical engineer. And not only was he fortunate in the age in which he lived, but he was wise in his choice of a place of residence. The fate of mechanical inventions is like that of the seed in the parable: the invention must fall on a proper soil, and be nurtured by favorable circumstances of time and place, in order to bloom into success. Thus Ericsson was early led from his home in Sweden to England, where he found a congenial environment till the conservatism of the English Admiralty drove him to this country. He was a man accustomed to carry through to useful perfection any scheme which commended itself to his mind; and, having confidence in himself, he found criticism difficult to endure. He knew he was right in his propeller for steam-vessels, and quickly left the country which refused to adopt it for America, where within two years the new device was in use on forty-two vessels. He knew he was right in his "Monitor," and was mortified and indignant at the hesitation of the American naval board in giving him a contract for building the first of this class of war-vessels. His work in each of these cases was not simply the devising of a form of propelling apparatus which would be better than the old side-wheel, or of a form of ironclad which was the best there was at the

time; but every mechanical detail of the "Princeton" and of the "Monitor" received some improvement at his hands.

Such was the man, and such was his work. He had the perseverance, the capacity to appreciate the importance of details, and the confidence in himself, which lead to success. And what was his reward? Doubtless he received considerable payments for much of what he did; but in the case of the "Princeton" it is said the government is still his debtor, and in that of the "Monitor" he received only the amount due him on his contract. As an inventor who supplied the government with an all-important engine of war, he received not a cent. Nor would he listen to the suggestion frequently urged on him by congressmen and others, that Congress should be asked to recognize his claim, and to provide for it. The Legislature of New York passed a resolution, thanking him for his services to the country, which he insisted on freely giving; and these resolutions he highly prized. Ericsson is said not to have cared for money, and this would certainly seem to be true.

The respect shown at his funeral was such as is seldom seen at that of any private citizen. The streets in the neighborhood of his late residence were crowded from the early morning hours with thousands, who for four hours passed through the house to pay homage to the departed genius. New York is a place full of human beings,—so full that each pays little or no heed to his neighbor; yet the great respect for this man of science and of action was shown in the number and character of those who followed his remains to their resting-place, in the uncovered heads as they were borne along the busy streets, and in the impossibility of admitting to Trinity all that wished. Ericsson was a man who could have endeared many to him, but he had a strong sense of duty to his work, which induced him to make few friends. This final homage of the unmindful crowds of the great city was to his genius well applied.

PUBLIC HEALTH A PUBLIC DUTY.

THE address of President Charles N. Hewitt, at the sixteenth annual meeting of the American Public Health Association, was full of suggestion, and contained many valuable propositions. It was entitled "Public Health a Public Duty," and dealt with the organization, powers, and relations of local, State, and National boards of health. In reviewing the work of the association, and the progress made in sanitary science during recent years, he said:—

"As secretary of one of the oldest of the State boards [Minnesota], I had the honor of an election as an original member of this body, and have known its history since. In my own State, beside, I have been missionary at large, and served as the organizer and counsellor of many a local board, and as sanitary inspector and health-officer as well. I have seen our organizations grow from two feeble boards with ill-defined powers, in 1872, to over fourteen hundred, united under a common code of law, with largely increased powers, duties, and funds. There is not to-day in Minnesota a community, however small, without such a board in direct communication with the State board.

"The State boards of health have increased from three in 1873, to thirty-one in 1888. Largely through their efforts, popular knowledge and confidence have grown from the tentative methods of the past to the demand for, and more liberal support of, sanitary organization and positive work. More and better legislation, great sanitary engineering works, and a bountiful crop of private enterprises in the same direction, are among the evidences that our field is widening and our responsibilities increasing. We have seen the early examples of efficient State executive organization become a living force in many more of the States and Canada. Various departments of modern science are our willing helpers. Microbiology has opened up great stores of discovery, and awakened great hopes, which we trust may not fail. We have seen the be-

ginnings of international co-operation for the crushing-out of cholera, yellow-fever, and other epidemics, which must in the near future become a beneficent reality, taking its place with arbitration, in international disputes, as the most valuable victories in our century.

"The first essential of any sanitary authority," Dr. Hewitt says, "is executive power, and its systematic use in the regular and scrupulous performance of every-day duty, as defined in the law and suggested by every-day experience. This almost self-evident proposition is constantly neglected in legislation for organization, and is very frequently violated by boards of health, who seem to favor the popular idea that an exceptional occasion is necessary to the highest exercise of their power, and infectious diseases of the classical type are their selection, with a proper admixture of panic. Panic is no advantage any longer, if it ever was, as a help to sanitary organization and work. Infectious diseases are not the leading causes of our sickness and mortality. It is only in the exceptional severity of plagues like yellow-fever, as it has prevailed in Florida, for example, that infectious disease counts the most victims in the sickness or death roll. That epidemics prevail at all, in our time and country, is somebody's fault: for, if there is one thing more than another that modern hygiene ought to be able to do, it is to forefend their attack, or control them if they effect a lodgement; and boards of health and health-officers have to learn that the most public and pronounced activity, after the invasion of infectious disease, is no substitute for the quiet, unobtrusive work which, in daily faithfulness, would have detected the first case, and controlled its spread. Another pressing need is a better classification of causes of death, for sanitary purposes, to which should be added causes of sickness and of permanent ill health from disease. At present our professional nomenclature is as vague sometimes as the popular one. Cholera-infantum and heart-disease are little more accurate than 'too weak to live,' a common popular cause of death under one year. The general divisions of the English registrar-general's tables are the best known, but some of the subdivisions are not satisfactory. Isolation has become so important and efficient an aid in the control of many diseases, that it is time to devise some changes in our customary methods which shall insure more thoroughness, with the least interference with the liberty of the family. It is a serious matter to restrain the bread-winning power of a laboring man or of his self-supporting children; and it is a still more serious matter to shut up a suspected family, sick and well, in a small house, when the removal of perhaps a single patient might save the rest, or some of them. The isolation home, under various names, is the ideal method of us all; but, if we had one always available, people must be educated to its use. We need it most for diphtheria and scarlatina. Another essential is an apparatus, not too expensive or elaborate, or too heavy for easy movement on wheels, for disinfecting clothing, bedding, and the like, by steam. One to which steam could be supplied by the boiler of a thrasher-engine would serve our country districts, and the same could be used where steam-boilers are available elsewhere. It could be taken to the infected house, charged, closed, and moved to the nearest available boiler, connected, disinfected, and discharged of its contents, with no danger, and at trifling expense. Still another need in this connection is a ready way of disinfecting the sick-room while occupied. Its essential feature should be the removal of the infected air and dust, disinfecting both as they escape, and the introduction of fresh air, so that quantity, temperature, moisture, and movement may be as required by the sick, but all to be done with the most complete protection of the well. The means must be easy, comparatively inexpensive, and available in the average houses of the laboring population. The stove, stove-pipe, or chimney, affords the available means in such houses in cold weather. In warm weather the open fire, gas, or kerosene, might serve to provide the means for exhausting the foul air and introducing that of the open in its place. Add to the simplest form of apparatus (the open fire or stove-pipe exhaust), cleanliness, fresh air, sunlight, thorough inunction, and boiling water for infected clothing of the sick and attendants, and you have a method almost everywhere practicable, which will reduce the danger from such diseases to the minimum, and the mortality as well.

"The very large mortality from non-infectious disease, under

five years of age, is, in the light of our present knowledge, no longer tolerable; and boards of health should move now, and positively, for its material reduction. By the last census this mortality was 43.7 per 1,000 of living population for the whole country, while in thirty-one registration cities it was 88.4 per 1,000. The mortality under five years to total of all ages was given as 39.8. The deaths under one year were, for the whole population, 120.9 in 1,000 living, while for the cities it was 267.5. This does not tell the whole story, as the statistics are estimated to fall from 15 to 30 per cent below the facts. We have no means of accurately estimating the sickness rate which accompanies this mortality, but may assume that it is enormous.

"Another subject of increasing importance, and which ought to receive the immediate attention of the State boards, is the sanitary relation of certain diseases of animals as communicable to man, notably tuberculosis, trichinosis, and glanders; and the increasing possibility that diphtheria and scarlatina may belong to the same class. The relations of the diseases of the cow to the influence of milk as food are attracting wide-spread attention, and, as affecting a very important infant food, deserve an attentive study with reference to sanitary control. On this subject, popular and certain professional opinion has, as usual, gone to extremes. From the use and even advocacy of distillery-milk, some have come to refuse the purest supply except after boiling, and their foolishness has been an acceptable and pecuniary advantage to the manufacturers of the proposed 'substitutes for cow's milk' which fill our markets and are tried on our children. The importance of the subject has resulted in making the control of infectious diseases of domestic animals one of the duties of the State and local boards of health, as in Minnesota, where the experiment has proven eminently successful and satisfactory.

"For the Nation and the States, the most urgent lesson is organization and efficient co-operation: for this last experience [of the epidemic of yellow-fever in Florida] but adds another to the accumulated evidence of the near past, that no State or province on this continent can afford to be any longer without a board of health officered by experienced men, who have the confidence of the people and governments they serve; supplied with unquestioned legal authority and sufficient money; and provided with every recognized means for dealing directly, and to the best advantage, with any disease of men or domestic animals threatening, or actually invading, the State. It must also, and for the same reason, have authority and funds to act with similar authorities of other States, in mutual co-operation, for State and national defence. It will not do to forget the established fact, that epidemics are now to be looked upon as evidences of the failure of public health, in organization or administration. That they occur, or spread, is presumptive evidence, when properly qualified authorities exist, that they neglected to take the needed measures, or were unable to take them. I see no escape from this conclusion, except it be shown, in any case, that prevention or control was beyond the resources of our art.

"A central State authority, organized and equipped as proposed, will find itself unable to do efficient preventive or restrictive work without thoroughly organized local sanitary authorities in every township, village, and city; and, further, each local board should have the same powers, and proportionate means, as the State board, in the locality it serves. Enforcing the common law, and independent in all purely local administration, the local authorities should be a unit for common purposes, under the State board, of which the control of infectious diseases is a conceded example.

"There are now in the United States thirty-one State boards of health. The first was organized in 1869, and others as well, before any attempt at national organization was made. Some of these boards are fully equipped with legal powers and funds for the work we have found laid out for them. The rest, with varying degrees of speed, are coming on to the higher level necessary for efficiency, and all are growing in usefulness and experience.

"State boards of health are established and recognized forces to-day; and any national organization attempted must, to be successful, be a development from them in form and function, for the purpose of carrying over to the nation, as a whole, the sanitary succor which the best of the State boards afford to the populations

they serve. A national board of health must first supply the national need proven to exist, by the conjoined efforts of the efficiently organized State boards, and fill up the full measure of that work within the national boundaries. So established, in the same dignified relation to the National Government that such State boards bear to the governments of the several States, it is prepared to perform the twofold duty, beyond our borders, which results from our present knowledge of the modes of approach and attack of infectious diseases. It must protect the nation, first, by a thorough knowledge of the character, location, and movements of such diseases abroad; second, by preventing, by the best-known methods, the shipping to this country of infected persons, animals, or things; third, by insisting upon competent sanitary service on board ship, with the best facilities for preventing, controlling, and crushing out any form of infection discovered on the passage out; fourth, by providing that the sanitary authority at the port of entry shall be fully informed of what is known of the sanitary history of the ship and her lading, up to the date of arrival, with later telegraphic report from the American consul and health-officer at the port of departure, if necessary.

"It is a fact that to-day, if it will, our government may learn all that is here proposed, by locating competent health-officers at the foreign shipping ports, whence our greatest danger comes, and might keep the seaboard quarantine authorities fully posted in these important particulars. As to those local authorities, it is time to call a halt in the criticism of their work till all sides in the controversy can be heard; or, better still, till health-officers of inland States can visit and see for themselves. Until the State boards agree in organization and powers, and in proper relations to local boards, the re-organization of the National Health Service upon a sufficient and permanent basis will be difficult, if not impossible."

THE RESOURCES OF THE NYASSA REGION, EAST COAST OF AFRICA.

FOR a number of years two English companies have been carrying on a profitable trade in the Nyassa and Tanganyika region, which, however, has recently suffered a severe check by the uprising of the Arabs against European influence. In a recent number of the *Journal of the Manchester Geographical Society*, Messrs. James Stevenson and E. O'Neill, consul of this district, give some interesting reports on the state of affairs and on the resources of this country, from which, and from some observations of other travellers, we take the following notes. Mr. Stevenson's paper is accompanied by an interesting sketch-map, reproduced here, showing the extent of the ravages of the slave-trade and the caravan routes in this region. The map will be of interest as supplementing the general map of Africa showing the extent of the slave-trade, published in *Science* of Dec. 28, 1888.

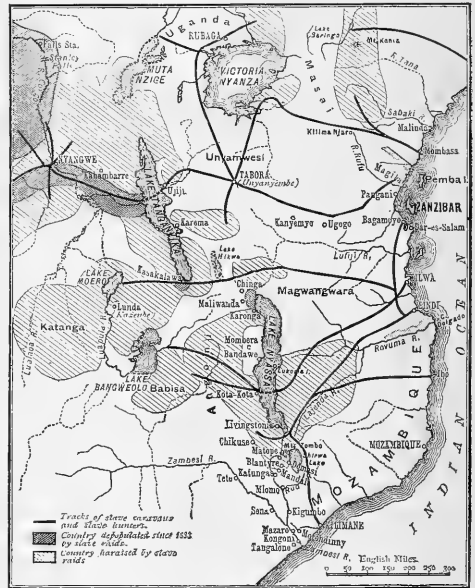

The produce of the Nyassa region, and the methods of trading, are well described by Mr. O'Neill. First in importance among the objects of trade is ivory. To this most valuable of all exports, — putting aside for the present any possible supply of minerals, — trade must chiefly look for an immediate return on its capital. Perhaps there are no better elephant-hunting fields in Central Africa than the great marshes of the Shire River and on the west coast of Lake Nyassa. The supply from these might be largely increased, to the benefit of trade, the country, and the people generally. The Arab slave-dealer is the chief collector of ivory in this country, with the tusks of which he loads his slaves, obtaining thereby cheap and profitable carriage to the coast. The British trader upon the Nyassa obtains but a fraction of the whole amount collected, — just so much as the Arab chooses to part with to enable himself to renew his supply of barter-goods, and to resume his collection in the interior. While the operations of the British trader on the Nyassa are confined to his station on the shores of the lake, he plays the dignified rôle of a storekeeper to Arab traders, where they may renew their store, and be relieved of a journey to the coast.

Much has been said of the check given to the slave-trade by the taking-up of the ivory on the Nyassa from the hands of the Arab collector, thus obviating the necessity for slave-carriage to the

coast. But it is certain that a very slight blow is struck by this means at the slave-trade. Little good will really be effected until the collection in the interior is also carried out by the whites, and the Arab trader is undersold, and thus peacefully ousted from the collecting-field. The British trader has every advantage on his side. Water-carriage should place his goods upon the Nyassa cheaper than they can be carried there overland by the Arabs, who have also to contend with the high percentage exacted from them for advances by the Indian trader of Zanzibar or Mozambique.

Next in importance to ivory must be placed India-rubber, in which the country west of Nyassa, stretching towards Lake Bangweolo, is undeniably rich; but comparatively little is collected, as the natives know little of the value of the plant, and have never been taught to collect it. Its export might probably be indefinitely increased by the same means which would help to extend the ivory-trade.

There are many other products indigenous to the country, but few of those known are able to bear the present cost of carriage to

markets. When the country comes to be better known, the number of more valuable products will be undoubtedly increased. Consul O'Neill says in regard to this point: "How completely valuable products may remain hidden until some chance brings them to light, I can instance by the case of *Strophantus Kombe*, of which some specimens were sent by me to the Foreign Office in 1881. A demand for it as a drug for heart-disease shortly after sprung up, and its existence in this country having been thus proved, I was able to start its collection in the Shire and Nyassa districts and in the Gaza country. The first consignment home proved to be so valuable to the collectors, that soon a rush was made to collect it, and the natives were quickly taught to bring down the pods in large loads. In the same manner we may hope other valuable products will come to light, and more profitable exports found than the oil-seeds which now form the staple articles of production on the coast and the lower Zambezi and Shire Rivers."

To estimate justly the probable development of this region, it must be remembered how slow and gradual has been the development of trade on the African coast. When the British Indian traders, to whom, a little more than a century ago, the Portuguese viceroy of India granted a monopoly of the trade of East Africa, arrived on

the coast, trade was precisely in the condition we find it now in the interior. The natives knew nothing of the collection of valuable products, — knew not, indeed, of their existence until shown. Now, on the coast, and for a hundred and two hundred miles inland, they have learned the demands of trade, and a regular collection is made by them of rubber, calumba, orchilla, and copal.

So far, we have spoken only of the export of produce indigenous to the country. When Europeans, however, begin to settle in it, — and in a small way this settlement has already begun, — fresh sources of wealth are opened up; and other products, for which the climate and soil are found favorable, are cultivated, and their export forms a valuable adjunct to that of the natural products of the country. Coffee and sugar have already been raised with success; and wheat, tea, and cinchona are all undergoing trial. The coffee and sugar consumed at the mission-stations are mostly home or Nyassa grown, and very good in flavor and strength. Recently Angora goats have been introduced for the production of mohair.

The climate of this region, which is from three thousand to five thousand feet above sea-level, is considered comparatively healthy, and, although it is not probable that it will ever become the home of a numerous white population, is well adapted to the establishment of plantations, worked by natives and managed by whites. The lake itself, which is only sixteen hundred feet above sea-level, has not as favorable a climate as have the slopes of the highlands.

The most important feature of the Nyassa region is its easy access. The uplands surrounding the Nyassa are divided by the only navigable waterway to the coast of Africa, and this alone marks it out as one of the first districts of East Central Africa for European occupation. There is nothing like it farther south, where European settlers are steadily advancing. To be able to step into a river-steamer at a seaport, as may be done now at the mouth of the Zambezi, and be carried up in five or six days to the foot of the Shire highlands, within a day's walk of the first settlements, is an immense step already gained. The new river-steamer plying on the Shire and Zambezi is a stern-wheeler, intended to carry seventy-five tons on a moderate draught. There is also a steamer of considerable size in course of construction on Lake Nyassa.

The trading company of Lake Nyassa, and the missions of that region, — the Free Church of Scotland Missions, which occupy the west coast of the lake; the Universities' Mission, which occupies the east coast of the lake, — have expended altogether some \$750,000 on this region. In pursuance of these objects, a survey was made of a road for about forty-six miles through the rough country of Lake Nyassa, towards Lake Tanganyika, which is reached from the terminal point of that road through an easy country. The road was made by native labor, and the traffic on it was at first worked by parties hired by the company from the Nkonde, Wanda, and Mambwe tribes, with all of whom the company made treaties by which its authority was recognized over these districts. At present its management has, however, slipped into the hands of the Arabs, who purchase goods at the Nyassa terminus, and convey them by their own people, often slaves, to Lake Tanganyika, the European staff being too limited in numbers to superintend all the stations required.

The steady advance of commerce in this region is seriously threatened by the progress of the Arabs, who have recently also invaded this country. For ninety miles along the south coast of Lake Tanganyika almost the whole population has been swept away or scattered, and in the adjoining fertile country of Ufipa the Arabs are now in great force.

During the last year, letters from the mission-stations expressed apprehensions, on account of the presence near Lake Nyassa of an Arab trader who had formerly made slave-raids in the Tanganyika region. These traders have congregated in numbers at the Nyassa end of the road, on account of the small steamer of the African Lakes Company having been for some time detained on account of disturbances. At various points besides the north end of the lake, the Arab invaders are ready, and have added to their old station at Kota-Kota one near Bandawe Mission; and besides Losewa and Makanjiva's, they have been aggressive near Blantyre.

All reports make it an undoubted fact that the question of commercial progress in Central Africa will solely depend upon the out-

come of the present struggle between Arabs and Europeans. The raids of the former are extending continually westward; and, wherever they have invaded a country, nothing but ruin remains. It appears doubtful whether the joint action of the European nations will succeed in breaking the power of the Arabs in the inaccessible fastnesses of Central Africa. It seems that the only means of success would be an absolute stoppage of the introduction of firearms, which would deprive the Arabs of a great part of their superiority over the native states.

BOOK-REVIEWS.

Occasional Addresses on Educational Subjects. By S. S. LAURIE. Cambridge, Eng., University Pr. 12°. (New York, Macmillan, \$1.25.)

PROFESSOR LAURIE, well known as lecturer on educational history and methods in the University of Edinburgh, here gives us another volume on his favorite themes. In it he touches on a great variety of educational topics, and handles most of them with ability as well as enthusiasm. Professor Laurie believes in the importance of studying educational theories and methods, and holds that no teacher is properly equipped for his work who has not been through a course of such study; and he gives excellent arguments and illustrations in support of this view. In regard to both subjects of study and methods of teaching, he is at issue with some enthusiasts of the present day, and especially with the advocates of manual training and competitive examinations. With respect to the latter, he takes the ground that competition in school is in its nature an evil, since it fosters "the desire to beat others, and exalt self over others," which he justly affirms to be anti-social. Moreover, he maintains that educational competition does not secure the best service to society. The whole lecture on this subject ought to be carefully read by American educators. He is opposed to free schools, and presents the well-worn arguments against them, but without adding any thing new.

With regard to subjects of study, Professor Laurie is a strong advocate of the humanities. He believes in technical schools in their proper place, but speaks slightly of manual training in ordinary schools, remarking, that, "if the spirit of man can be educated through his fingers, it is a pity that Plato and Shakspeare ever wrote, and Christ ever taught." The end of education, in his view, is not to make good workmen, but good men; and his school curriculum is arranged accordingly. He would abandon Greek as a required study, because of the importance of French and German, and would base the course of study in secondary schools on English and Latin. He has a strong and, we think, sound sense of the educational importance of literature, especially in its moral and æsthetic aspects; and he would also devote considerable time to national history and politics. Of the physical sciences he would teach only geography, which seems a very narrow view; though it must be added that he would have geography taught in a very wide and liberal spirit. In mathematics he would teach only the elementary branches; and in French and German, as much as there is time for. This programme is sure to provoke criticism, from the scientists at least; but Professor Laurie is evidently not averse to controversy. His whole book is very suggestive, and we trust will not be overlooked by any one interested in education.

A Treatise on Hydraulics. By MANSFIELD MERRIMAN. New York, Wiley. 8°. \$3.50.

This volume is intended mainly for the use of students in technical schools, and consequently the subject has been treated, and the material selected and arranged, with a view to meet the requirements of such students. The author, who is professor of civil engineering in Lehigh University, is gifted with a perspicuous and pleasing style, and has produced a book which will without doubt prove an acceptable text-book upon the subject. A brief interesting chapter is devoted to the units of measure, physical properties of water, atmospheric pressure, gravity, and computations. A few hints on methods of study, appended to this chapter, would be of service to students in any department of science. Then follow in regular order chapters on hydrostatics, theoretical hydraulics, and the flow of water through orifices, over weirs and in

tubes, pipes, canals, and rivers. The measurement of water-power, the dynamic pressure of flowing water, hydraulic motors, and naval hydro-mechanics are treated in separate chapters, the latter subjects being given less space than their importance would seem to warrant. The book is amply illustrated.

A General Formula for the Uniform Flow of Water in Rivers and other Channels. By E. GANGUILLET and W. R. KUTTER. Tr., with additions, by Rudolph Hering and John C. Trautwine, Jun. New York, Wiley; London, E. and F. N. Spon. 8°. \$4.

To all engaged in the study of hydraulic problems, as well as to engineers who deal with the flow of water, this book will be of great service. It is the first published translation of the authors' chief work on the subject; though unauthorized translations from articles in German periodicals on this subject, by the same authors, were published in London several years ago. The first part of the work is devoted mainly to historical matter, and to a review of present knowledge of the laws governing the flow of water. A treatise on the new formula, showing its close agreement with a large number of experimental results obtained under differing conditions, makes up the second part. A supplement contains a more direct method of deriving the formula, for the benefit of those who desire mathematical brevity. A second general formula is also sketched, though not made prominent, as the first one is considered preferable.

The translators call attention to the fact that the authors have been erroneously regarded as holding their formula to be scientifically perfect, and covering both possible and impossible conditions of flow. They disclaim for them any such intention, insisting, that, as the formula is purely and essentially empirical, it must not be expected to apply to cases beyond the range of the data from which it has been derived. Its application is limited to cases where the slope of the water-surface can be ascertained with a degree of accuracy sufficient for the given case.

Nine appendices and five tables for practical use, which form part of the volume, contain much additional matter of value to those interested in the subject. In Appendices I. to IV. are given extracts from the works of Mr. Kutter upon the formula. Appendix V. contains directions for constructing the diagram used for a graphical solution of the formula. Appendix VI. is devoted to Kutter's modification of Bazin's general formula, useful for special purposes because of its simplicity. In Appendix VII. are given a number of formulæ and data concerning the relation between the mean and surface velocities in streams; the views of a number of investigators on velocities beyond which a scouring of the bed takes place in channels formed of different materials, are given in Appendix VIII.; and an account of Harlacher's method of ascertaining the discharge of rivers, in Appendix IX.

In Table I. are collected the hydraulic elements of over 1,200 gaugings, made in 300 different channels and pipes, under varying conditions of mean hydraulic depth and slope. In the original work the corresponding table is confined to 81 gaugings; so that this table is virtually the work of the translators, who believe it to be the most complete and comprehensive one yet published. The other tables contain the computed values of different elements of the formula, and the conversion of units of measure. An immense amount of labor has been bestowed upon this work by translators as well as authors.

AMONG THE PUBLISHERS.

THE delay in the publication of Sir Monier Williams's book on Buddhism has been caused by difficulties which have arisen in connection with the illustrations. A certain number of copies will be in Mr. Murray's hands at once. The work will be published in America by Macmillan & Co.

— Lee & Shepard have in press Samuel Adams Drake's "Decisive Events in American History, Burgoyne's Invasion of 1777, with an Outline Sketch of the American Invasion of Canada, 1775-76." It will be an admirable historic narrative, intended to be used as a text-book, or as a supplementary reader in schools, as well as for general reading. A valuable book, arranged especially for

young people, yet by no means unsuited to any time of life, entitled "Every-Day Business: Notes on its Practical Details," by M. S. Emery, will be published soon by this house. It gives careful instruction regarding many matters closely connected with business transactions. The book will be a valuable companion for young people, and its pages will contain instructions on business subjects, being designed for ready reference, and also as a text-book for use in schools.

— Macmillan & Co. will publish shortly "Natural Inheritance," by Francis Galton; a second series of Sir John Lubbock's "Pleasures of Life;" and A. R. Wallace's work on Darwinism.

— Harper & Brothers will publish this month the second volume of W. P. Frith's "Autobiography and Reminiscences," and a new and revised edition of the "Manual of Historical Literature," by President C. K. Adams of Cornell.

— Wolcott & West, Syracuse, N.Y., will shortly publish "Theories of Knowledge," by Rev. W. D. Wilson, D.D., Professor Emeritus in Cornell University.

— D. C. Heath & Co. have just ready, in their series of Guides for Science Teaching, "Hints for Teachers of Physiology," by Dr. Henry P. Bowditch of the Harvard Medical School. It will show how a teacher may supplement his text-book instruction by simple observations and by experiments on living bodies or on organic material.

— Dodd, Mead, & Co. have in preparation the letters and diaries of Emin Pacha, which, besides containing matter of interest as biography, relate largely to the author's scientific investigations. The volume has for an introduction a biographical sketch of Emin, with two portraits, one of them recent. They have also in press Bayard Tuckerman's biography of Lafayette, to be issued in two volumes.

— T. Y. Crowell & Co., in connection with the announcement of a cheaper cloth and a paper edition of Tolstoi's great work, "Anna Karénina," translated by Nathan Haskell Dole, state that Mr. Dole's translations have been received with great favor by the Tolstoi family. In a recent letter to Mr. Dole, the Countess Tatiana Lyovna Tolstoi says, "My father has read your translations, and is much pleased with them. They are to his mind very carefully and accurately done."

— Ulric Blickensderfer, Chicago, Ill., has just issued "Blackstone's Elements of Law, etc.," with analytical charts, tables, and legal definitions, arranged and displayed by a systematic and attractive method. Mr. Blickensderfer is an attorney-at-law, and claims that these charts will be found time-saving helps to his colleagues. Sample copies may be had on application. He also has published a chart of the "Historical and Genealogical Descent of the Crown of England," which by an ingenious arrangement of types brings the history of England on one side of a sheet of paper six inches wide and eighteen inches long, which folds up like an ordinary legal document. The succession covers from A.D. 827 to the ascent of Queen Victoria in 1837.

— The article on "Climbing Mount St. Elias," to appear in *Scribner's* for April, is the work of an American member of the Alpine Club, Mr. William Williams, who, with two English fellow-members, succeeded, during the summer of 1888, in reaching the highest point ever attained on that mountain, — about 11,400 feet. Charles Francis Adams, president of the Union Pacific, will contribute a railroad article to the number, on the "Prevention of Strikes." He proposes a plan which, if carried out, would be almost a revolution in the relations of railroad employers and employees. William H. Rideing, who made a careful inspection of the great Clyde ship-yards during the past summer, will give a description of them, showing the various stages in "The Building of an Ocean Greyhound."

— Ticknor & Co.'s March books include "Dragon's Teeth," translated from the Portuguese of Eça de Queiroz, by Mrs. Mary J. Serrano; and in their Paper Series, "Forced Acquaintances" (No. 53), by Edith Robinson, and "Under Green Apple Boughs" (No. 54), by Helen Campbell.

— An important undertaking is promised by the Leonard Scott Publication Company, in the American edition of the *Nineteenth Century* for March, in the shape of an American supplement containing a series of papers by some of the foremost of our educators on the relation of examinations to education. This subject has attracted considerable attention in England of late, having been started by the "Signed Protest" in the November *Nineteenth Century*. The present papers, presenting the subject from an American standpoint, will be by ex-President McCosh of Princeton, Presidents Adams of Cornell, Angell of the University of Michigan, Carter of Williams, Eaton of Marietta, Gilman of Johns Hopkins, Magill of Swarthmore, Pepper of Colby, Rhoades of Bryn Mawr, and Sharpless of Haverford; Chancellors John Hall of the University of the City of New York, and Sims of Syracuse; Professors Cook of the University of California, Harper of Yale, Harris of Concord, Hunt of Princeton, Rogers of Haverford, and David Swing of Chicago; Rev. Dr. Crosby, Hamilton W. Mabie, Esq., and Barr Ferree, Esq., of New York. Dr. William H. Burnham will also contribute, and Professor Thompson of the University of Pennsylvania. The symposium promises to form a most important contribution to the discussion of a very difficult question of educational methods. The March number of the *Nineteenth Century*, in addition to the papers on education and examination in the American supplement, will contain an article by Mrs. Humphry Ward, the author of "Robert Elsmere," on the new reformation as viewed from her own standpoint. Professor Huxley writes on "The Value of a Witness to the Miraculous;" and the review contains criticisms on his paper on agnosticism in the February number, by the Rev. Dr. Wall, principal of King's College, and Dr. Hagee, bishop of Peterborough.

— The *Popular Science Monthly* for April will contain a scientific explanation of the power to insnare the human mind possessed by the leading delusion of the present day. The article is by Professor Joseph Jastrow, and is entitled "The Psychology of Spiritualism." It contains accounts of the manifestations by the Fox sisters, Dr. Slade, Englington, and other mediums, all of which have been proved to be "gross intentional fraud throughout." Professor Huxley has written a racy reply to certain criticisms of agnosticism made at the Church Congress of 1888, and to a recent deliverance by Frederic Harrison, who attempts to prophesy on this subject. The article contains an account of how the name "agnostic" originated, and explains why agnosticism, as Professor

Huxley conceives it, cannot have a creed. It will also be published in the April *Popular Science Monthly*, as will an article on "The Chemical Elements," by Professor Josiah P. Cooke of Harvard, telling the story of the changing beliefs about what substances are made of, from the time when earth, water, air, and fire were thought to be the elements of all things, down to the present day, with its list of over seventy simple substances, and when the idea is gaining ground that perhaps there is only one kind of matter, after all.

— The paper in the *Political Science Quarterly* for March will attract most attention is that by Mr. H. O. Arnold-Foster, on "Irish Secession." It gives what is probably the best presentation of the Unionist argument that has appeared in this country, and should be carefully read by every one desirous of understanding the question at issue. The author takes up the home-rule arguments one by one, and gives a conclusive answer to some, at least, of them; while at the same time he presents very forcible considerations to show that an Irish parliament is equally undesirable for England and for Ireland. Another article of interest is that by A. Gauvain, on "The Crisis in France." M. Gauvain is deeply impressed with the low character of French political life, with the feebleness of the senate and the fickleness of the Chamber of Deputies, and with the instability of the administration; and he evidently views the future with some alarm. He affirms, as other observers have done, that there is no statesman of ability in the country, and that the republicans are drifting towards radicalism. Meanwhile the monarchists are gathering strength, and, with the aid of the Boulangists, stand a good chance of carrying the coming elections. The *Quarterly* has still another article on foreign affairs, that by Professor Gustav Cohn, on "Income and Property Taxes in Switzerland." Injustice has often been done in all countries to the poorer classes by raising too large a portion of the national revenue by indirect taxation; and Professor Cohn here shows how the Swiss have endeavored to remedy this by laying a large share of the burden on property and income. Mr. H. L. Osgood has a paper on "Scientific Anarchism," in which he traces back the doctrine to Proudhon as its real originator, and then shows what changes it has undergone at the hands of the "Individualistic Anarchists" and the "Internationals," concluding with a brief but decisive argument against the whole scheme. Besides the various essays, the *Quarterly* has an extended review of Bryce's "American Commonwealth," by Professor Woodrow Wilson.

READY MONDAY, MARCH 11.

JANUS.

By Edward Ireneus Stevenson, author of 'The White Cockade,' etc. 12mo, cloth, \$1.00; paper covers, 50 cents.

A dramatic and powerful romance with an art motive. Built upon a musical theme, a succession of brilliant scenes and situations hurries the reader onward to the end without a moment's pause. The work will have an especial interest for lovers of art and music; but in the vigorous action of the story, the contest of passion with honor, the infidelity of the wife, the betrayal of the friend, and the tragic climax, there is likewise interest for every class and condition of readers.

AN AMERICAN VENDETTA.

By T. C. Crawford, late London Correspondent of the New York World. Illustrated fully by Graves. 12mo, cloth, \$1.00; paper, 50 cents.

This book contains a series of most graphic pictures of a land of barbarism, few could imagine possible to find in this country of boasted freedom and civilization.

THE POSITIVE PHILOSOPHY.

By Auguste Comte. Translated by Harriet Martineau. Large 8vo, cloth, gilt top, large new type. Price, \$4.00.

This is a translation, by a strikingly clever mind, of the great philosopher who has been called the Escon of the Nineteenth Century, in handy shape, and brought within reach of all orders of readers. The translation of this grand monument of human genius is in itself a masterpiece.

LEAVES FROM A DRUMMER'S DIARY.

By Charles S. Plummer. 12mo, cloth, \$1.00; paper covers, 50 cents.

A neat and compact work, of sterling value to the Commercial Travellers of the United States, to whom it is dedicated, and an indispensable companion to any Drummer, young or old, who would succeed on the road. The information it contains is clear, practical, and of obvious importance, touching as it does every fibre of the drummer's duty, whether as to his customers or his employers. In it the Drummers tell their funny experiences and indulge in a constant flow of wit and humor. The book can be read with profit and pleasure by any person.

ROUSSEAU'S CONFESSIONS

Superbly illustrated and with a portrait of the author. By Jean Jacques Rousseau. Large 12mo, gilt top, 3 vols. in 1. Price, \$1.50.

Rousseau, the Man of Nature, who with his pen overthrew the French Monarchy, and smote the head off the sixteenth Louis, never wrote so bitterly, so pathetically, so divinely, and so meanly as in "The Confessions."

ROCHEFOUCAULD'S MORAL MAXIMS.

With steel portrait of the author. Large 12mo, gilt top. Price, \$1.00.

"Hypocrisy is the homage which vice renders to virtue," is a phrase which would alone have entitled Rochefoucauld to fame.

A BLUE-GRASS THOROUGH-BRED.

By "Tom Johnson." 12mo, cloth, \$1.00; illustrated paper covers, 50 cents.

A richly colored panorama of scenes and incidents in the Blue-grass region of Kentucky. The reader is borne breathlessly onward through a series of charming live episodes, horse-races, an attempted murder, the terrible revenge of a wronged husband, and a clever Wall Street exposé. Above all towers the gallant and knightly figure of the noble Thoroughbred himself.

OUR PARIASHS AMONG THE TRAMPS.

By Uncle Tim. 12mo, cloth, \$1.00; paper covers, 50 cents.

A volume of rare interest and information from the pen of a writer thoroughly conversant with that philosophy which bears upon the well-being of society and every-day life. It presents its arguments in a most attractive form and in the guise of absolute experience.

HIS FATAL SUCCESS.

By Malcolm Bell. With Illustrated Cover by E. Hamilton Bell. 12mo, cloth, \$1.00; paper covers, 50 cents.

A novel founded upon the occult, but in an entirely original manner. The possibilities suggested by this story are startling, almost terrifying, and might well serve as a warning to the many who in these days are blindly groping into the spectre-haunted gloom of Spiritualism and Theosophy.

BELFORD, CLARKE & CO., Publishers, New York, Chicago, and San Francisco.

— Houghton, Mifflin, & Co. have just issued a new life-size portrait of Dr. Holmes, which is even better than the earlier one.

— Charles Scribner's Sons have in preparation a handsome popular library edition, in four 12mo volumes, of Bourrienne's well-known "Memoirs of Napoleon," a standard work of which many hundreds of imported sets have been sold every year. This new edition will be an exact reprint of the latest English edition, and will contain the thirty-eight portraits of the original, together with all the other features that give distinction to the work. The price will be sufficiently low to bring these volumes within reach of all would-be readers.

— G. P. Putnam's Sons have in press, as their own commemoration of the centennial anniversary of the inauguration of Washington, a unique limited edition of Irving's "Life of Washington,"—a work for which Bryant predicted "a deathless renown." The set will be issued in five volumes, handsomely printed in large quarto form, and will contain 200 illustrations, comprising 130 steel plates and 70 woodcuts printed on India paper and inlaid in the text. The plates include portraits of all the noteworthy generals and statesmen of the American Revolution. But 300 sets will be issued, and the type will be distributed as printed from. The price to subscribers has been fixed at \$50.

— Mrs. Stowe has been able to revise the biography of herself, written by the Rev. Charles Stowe and Mr. Kirk Munroe. It will be published at an early day by Houghton, Mifflin, & Co.

— Baron Grancy will shortly issue, in Paris, a volume on American customs. It is to be in the shape of a novel, to be entitled "A French Ranch in Dakota," and will treat wholly of Dakotan affairs. The author, according to a despatch to the New York *World*, is the original founder of the Fleur de Lys settlement of French horse-breeders, whose life in Dakota this book is meant to describe.

LETTERS TO THE EDITOR.

* * * Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith.
The editor will be glad to publish any queries consonant with the character of the journal.
Twenty copies of the number containing his communication will be furnished free to any correspondent on request.

An Acoustic Mill.

WHEN a vibrating tuning-fork is brought near to a light body, like a pith-ball or a small piece of paper, the latter moves towards the fork as if attracted by it. This phenomenon was observed by Guyot in 1832, and was rediscovered by Guthrie in 1870. It has been supposed by some that gravitation could be explained by the vibratory motions, such as atoms and molecules are known to have; but it does not appear that gravitation sustains any quantitative relation whatever to the temperature of a body, such as would be the case if molecular vibration was the cause of it. The observed phenomenon may be accounted for thus. When the prong of the tuning-fork beats outwards, the air is driven before it and is condensed, while behind it there is a partial vacuum. If the velocity of the prong was greater than that of a particle of air in its free path movement, then there would be a complete vacuum behind the prong. As the latter beats to and fro, it is obvious that the density of the air adjacent to the prong must be less than if the latter was at rest, the difference depending upon the relative velocity of the prong to that of the molecules of air in their free path movements. As the pressure of the air varies as its density, it follows that the air-pressure is less in the neighborhood of the vibrating fork than at a distance from it. Hence, if an object is near to the vibrating fork, the air-pressure will be greater on the remote side, and will push the object towards the source of vibrations.

Numerous devices have been invented by Doornak and Strop to illustrate this principle. Most of them are too complicated and costly to be had by more than a few. The following is simple enough, and can be available for any one having a Chladni plate.

Cut a disk three or four inches in diameter out of letter-paper, and then cut eight or ten radial slits from the circumference half-way to the centre, and turn up one edge of each sector so as to form a kind of paper windmill. Suspend this by a thread from

its centre, and see that it hangs horizontally, which may be done by fixing a bit of beeswax to the middle of the disk, and have the thread go through it. Adjustment will be easy and quick by slight pressure upon the wax, changing the relative position of the thread.

This disk may now be brought over a properly mounted Chladni plate near the edge, and as close to it as possible, while allowing it free space for rotation without touching the plate. If the plate be made to vibrate vigorously, the disk will begin to spin, turning in the same direction as if a current of air were blowing upon it from above. The lower components of the sound of the plate will be necessary to make so large a disk as the above to spin, as the higher ones have too many nodes. The fundamental is the best; and, if it can be produced with an amplitude of an eighth of an inch or more, the disk will go round two or three times a second. Of course, the bow should be drawn across the edge opposite to the disk, in order to prevent a node being formed underneath it, and also to avoid the disturbance from movements of the air. I have found that the fundamental vibration of the Chladni plate can more easily be produced by bowing it with a round wooden rod well rosined, than with the ordinary violin-bow. In this experiment the pressure of the air is lessened between the nodes at the surface of the disk, and the space thus affected extends to the height of an inch or two. It is also evident that the light dust that moves to the place of greatest disturbance is moved there by the difference in air-pressure instead of by little whirlwinds caused by the vibrations, as it was explained by Faraday.

A. E. DOLBEAR.

College Hill, Mass., March 5.

Note on the Robinson Anemometer Constant.

THIS is the factor by which the velocity of the central point of the cups is reduced to the actual velocity of wind. When Dr. Robinson first invented his anemometer in 1860, he determined the value of this factor, for all patterns of the instrument, to be exactly 3, and this has been in use for all patterns ever since. But by the experiments of Dr. Dohrandt at St. Petersburg in 1878, this constant, for the Kew pattern at least, was found to be much less, which led Dr. Robinson to repeat his experiments; and the result was a confirmation of Dr. Dohrandt's result, and showed that his own factor is erroneous. Experiments at the Deutsche Seewarte in Hamburg have also given a factor much smaller.

The labor of the wind-force committee of the Royal Meteorological Society, referred to in my previous note (*Science*, xiii. p. 171), has been directed mostly toward determining this factor for several anemometers of different patterns, which are as follows:—

	Arms.	Diam. of Cups.
	Inches.	Inches.
Kew Standard	24.00	9.0
A 19	5.80	4.0
A 21	6.75	2.5

These were placed near the end of a long arm of a whirling apparatus, moved by a small steam-engine with varying velocities. The number of turns of the anemometer compared with that of the whirling apparatus during any given time of uniform velocity, the relations between the length of the arm of the anemometer and the distance on the arm from the centre of whirling being known, gave the ratio between the velocities, and so the value of the constant, which is found to be about the same for all, except very small velocities.

The average of 58 experiments with the Kew Standard gives 2.15 instead of 3 for the value of this constant. From 51 experiments made with A 19, the value 2.51 was obtained, while the average of 49 experiments with A 21 gave 2.96, which is very nearly that determined by Dr. Robinson, and now in use. It is seen, therefore, that while the Robinson factor is very erroneous for the Kew pattern, and also for A 19, but especially the former, it is very nearly

correct for A 21. The use of the factor 3 for all patterns of anemometers now for nearly thirty years has introduced a great amount of error in published wind velocities; so that they are not only not comparable generally with one another, but the errors have likewise affected most, if not all, the results obtained from the discussions of these velocities. It is much to be regretted, therefore, that some standard pattern had not been adopted and its constant accurately determined at the start, instead of deferring it for nearly thirty years; for, if this is even now done, it will be a long time before any adopted standard and its true constant can come into general use.

Since the force of the wind is as the square of the velocity, errors in the estimated velocity of the wind give rise to errors in the pressure of the wind which are proportionately more than twice as great. For instance: if the true velocity of the wind is 30 miles per hour, the Kew Standard with its factor 3 makes it 42 miles nearly, an increase in the ratio of 1 to 1.4; but the force of the wind is increased in the ratio of 30^2 to 42^2 , or as 1 to 2 nearly, and so in a ratio more than double the preceding one. In estimating the force of the wind from the indications of the anemometer, the effect of the error in the factor 3 of the anemometer, and of the wind-pressure constant .005, now in general use, are both in the same direction; so that the combined errors of both are very great. For instance: in the case of a wind of 30 miles per hour, we have seen above, that the error of the factor 3 applied to the Kew Standard increases the force of the wind in the ratio of 1 to 2; and if the wind-pressure constant should be .003 instead of .005, then the effect of both errors is to increase the estimated force of the wind above the true force in the ratio of 1 to $2 \times \frac{5}{3}$, or to more than three times the real force. Of course, this is an extreme, but not an impossible case; for in anemometers mostly used the error of the factor 3 is not nearly so great as for the Kew Standard, and the true value of the wind-pressure constant may come out a little more than .003 when accurately determined, but still the errors of estimated wind forces, with the constants in use, are undoubtedly enormously large. Mr. Whipple, of the wind-force committee, says, that, "unless the Robinson anemometers could be put into the hands of those who would take care of them, their indications were frequently worse than useless. The instruments require to be continually looked after. Even if carefully attended to and regularly cleaned and well oiled, their records are far from satisfactory."

It is the opinion of the writer that they must in time give way to something better, probably to Mr. Dines' newly invented helioid anemometer, which is more simple in its mechanical action, and, according to the experiments made with it, seems quite satisfactory. A description of this instrument is found in the *Quarterly Journal of the Royal Meteorological Society* for July, 1887.

WM. FERREL.

The Soaring of Birds.

THERE can be no doubt that the explanation of soaring given by Mr. Gilbert is mechanically sound. The only remaining question seems to be as to its sufficiency. In regard to this question, the following considerations may be of service:—

There is a certain velocity relative to the air such that a bird possessing it can be sustained against gravity without muscular exertion. Let V represent that velocity for a given bird. Let there be two horizontal layers of air, whose relative velocity is z . For simplicity, let the velocity of the lower layer be zero, that of the upper z . Suppose the bird at some instant to be in the upper layer, moving in the same direction with it, and with a velocity relative to it of V , so that he can just be sustained while moving horizontally. His velocity relative to the lower layer is $V+z$. Let him now descend into the lower layer and wheel horizontally 180 degrees. In so doing he necessarily loses some energy, and his velocity decreases. Now, in order that he may be sustained at the same level during the wheeling, his velocity relative to the lower layer must not fall below V . Suppose his decrease of velocity to be a little less than z ; he will then be moving opposite to the direction of the upper current, with a velocity greater than V . He can therefore not only maintain his level, but can rise. Let him now enter the upper layer, his velocity relative to it being $V+z$. If, now, he

can wheel horizontally through 180 degrees without losing more than the velocity z , he will be in a position to repeat the cycle.

The statement of Professor Oliver in *Science* (xiii. p. 16) seems to imply that the difference in velocity of the air-currents needs to be as great as the relative velocity which will enable the bird to sustain himself against gravity; that is, that z must be as great as V . If the discussion here given is correct, such is not the case. It is only necessary that the bird should have initially a sufficient relative velocity, and should be able to wheel horizontally 180 degrees without losing by "friction" enough energy to reduce his velocity as much as z , the velocity of one air-current relative to the other.

L. M. HOSKINS.

University of Wisconsin, Madison, March 5.

"Shall We Teach Geology?"

WHEN a reviewer bases critical verdicts on ignorance or misapprehension of the work reviewed, he has an advantage over the author, of which, in my own experience, I usually leave him in quiet possession. Still the meekness of silence may not always prove most useful to the public. Your reviewer of my work, "Shall We Teach Geology?" in No. 317, says that I ignore the mental and moral sciences as means of culture; but he should have observed that I do not undertake to discuss the education value of all sciences and literatures, but only of those selected as types by certain pedagogical writers who hold geology in disesteem. Your reviewer states that I mention "history only to slight it, declaring that it trains no faculty but verbal memory." My criticisms on history contemplate it as a study urged upon children in the early stages of education. This is what I have recorded on purpose to forestall such an accusation. "My present investigation concerns studies as usually taught and in schools of the lower orders. In college, history and literature are pursued in a nobler and more cultural way" (p. 148). Your reviewer employs the term "literature" in the wide sense, which makes it a much more valuable thing than literature as used in the narrow sense of the author, whose positions I am examining (note, p. 145). Your reviewer states, also, that I claim for geology that "the subject should be taken up in the primary schools, and pursued every year as long as the student attends school." This is preposterous criticism. Such is not my position, nor is the idea anywhere conveyed. I think the subject should be taken up briefly, two, three, or more times, at successive stages of mental development, not completed in one course late in school-life (see pp. 133, 134).

ALEXANDER WINCHELL.

Ann Arbor, Mich., March 5.

To keep Water-Mounts Moist.

In my last communication on this subject (*Science*, xiii. p. 170) I recommended glass capillary tubes. I since find that a much simpler plan, and one that serves equally well in most cases, is to suspend from the edge of the cover-glass, to a beaker of water beneath, a moistened piece of filter-paper about four centimetres long and half a centimetre wide.

Likewise, in the study of germination of seeds, the capillary tubes or the moistened filter-paper may be put to good service. Very clean and satisfactory specimens of the first stages of germination may be obtained by placing the moistened seeds in contact one with another on a glass slip over a beaker of water, and suspending from their midst to the water one of the tubes or simply a narrow piece of paper. A bell-jar will exclude dust.

E. B. KNERR.

Parsons College, Fairfield, Io., March 6.

The Wind-Pressure Constant.

IN my note I see you have put Hazen for Hagen. The latter is a German physicist of Berlin. Will you please make the correction in your next number? This is important, since Hazen has also made experiments, the results of which differ very much from Hagen's, and it may seem that I have misrepresented his results.

GUARANTY INVESTMENT COMPANY

CAPITAL \$250,000.

Offices: Atchison, Kan. 191 Broadway, New York. 222 Walnut St., Phila.

Hon. ALBERT H. HORTON (Chief Justice, Kansas Supreme Court), Topeka, Kan., Pres't.

7% Guaranteed Farm Mortgages 7%

The Guaranty Investment Company makes loans upon fertile farms in the choicest portions of Kansas and Nebraska and has adopted the policy of sending a Committee of its Investors each year to examine its loans and methods of business.

The Committee this year consisted of PROF. A. H. BERLIN, Principal of the High School Montrose, Pa., and MAJ. THEODORE L. POOLE, Ex-U. S. Pension Agent, Syracuse, N. Y. Both of these gentlemen are persons of the highest character and have the confidence of the Communities in which they reside.

The Committee has recently returned and has made a very interesting Report upon the general development of Kansas and Nebraska as well as the business of the Company. The Company will be glad to send this Report to any address.

The following names are taken from the long list of Investors in our Mortgages:

(See if Some Friend of Yours is not in the List.)

William A. Caudwell, 59 Liberty St., N.Y.
 Palmer Cox, 68 Broadway, N.Y.
 Rev. Jos. B. Ryland, D.D., 11 Livingston Place, N.Y.
 Rev. Brady E. Backus, D.D., 360 West 28th St., N.Y.
 Rev. R. M. Sommerville, 126 West 45th St., N.Y.
 Dr. Robert A. Murray, 235 West 23d St., N.Y.
 Dr. James P. Tuttle, 156 West 41st St., N.Y.
 H. Edwards Rowland, 218 Fulton St., N.Y.
 Irving H. Tift, Esq., 272 Broadway, N.Y.
 Prof. D. G. Eaton, 53 Pineapple St., Brooklyn, N.Y.
 Dr. E. P. Thwing, 156 St. Marks Ave., Brooklyn, N.Y.
 Dr. C. C. Miles, Greenport, N.Y.
 John V. N. Bergen, Port Jefferson, N.Y.
 Benj. W. Stillwell, Yonkers, N.Y.

R. C. Coleman, Goshen, N.Y.
 Mrs. Samuel Carlisle, Newburg, N.Y.
 Dr. C. C. Bartholomew, Ogdensburg, N.Y.
 Rev. Nelson Millard, D.D., Rochester, N.Y.
 Rev. Horace G. Hinsdale, D.D., Princeton, N. J.
 Dr. Charles M. Howe, Passaic, N. J.
 George A. Skinner, 5 Railroad Place, Newark, N. J.
 Dr. Edwin M. Howe, 85 Halsey St., Newark, N. J.
 Dr. H. G. Buckingham, Clayton, N. J.
 Dr. Martin Cole, Jr., Hainesville, N. J.
 Mortgage Trust Co. of Pa., Philadelphia, Pa.
 Miss Mary Miller, 1220 Spruce St., Philadelphia, Pa.
 Henry D. Biddle, 317 1/2 Walnut St., Philadelphia, Pa.

Dr. Calvin C. Halsey, Montrose, Pa.
 Rev. William Baldwin, Great Bend, Pa.
 Gen. William Lilly, Mauch Chunk, Pa.
 Second Nat. Bank, Mauch Chunk, Pa.
 Enos E. Thatcher, West Chester, Pa.
 Mrs. Townsend Poore, Scranton, Pa.
 Rev. Burdett Hart, D.D., New Haven, Conn.
 Dr. Frank H. Wheeler, New Haven, Conn.
 Charles R. Christy, Stamford, Conn.
 Mrs. Catharine P. Fuller, Woodmont, Conn.
 Miss Jessie Henderson, Lenox, Mass.
 Dr. M. J. Halloran, Worcester, Mass.
 Albert Walker, Bennington, Vt.

Address for Report and Monthly Bulletin

HENRY A. RILEY, General Eastern Manager, 191 Broadway, N.Y.

ONE LANGUAGE FOR THE WHOLE WORLD.

WORLD-ENGLISH :

THE UNIVERSAL LANGUAGE. 25 CENTS.

EVERY one has heard of the butcher who, after a long search for his knife, at last found it in his mouth: so speakers of English have been seeking for a universal language, when, lo! it is in their mouths. The intelligibility of English words has been obscured by a dense mist of letters. This is now dispersed by A. Melville Bell, who has already won a world-wide reputation through his invention of "Visible Speech," the great boon to deaf-mutes. Professor Bell calls this new discovery of his "World-English," and the result is a language which cannot fail to meet with acceptance, and at once supersede the supposed necessity for "Volapük," or any other artificial language. No language could be invented for international use that would surpass English in grammatical simplicity, and in general fitness to become the tongue of the world. It is already the mother-tongue of increasing millions in both hemispheres, and some knowledge of the language is demanded by all educated populations on the globe. Social and commercial necessities require that the acquisition of this knowledge shall be facilitated, and it is believed that Professor Bell's invention has removed the last impediment to English becoming the universal language, for which vague desires have long been entertained, although hitherto only futile efforts have been made.

Ex-President Andrew D. White, of Cornell University, says: "I believe that the highest interests of Christian civilization and of humanity would be served by its adoption. China and Japan would be made English-speaking peoples within fifty years, and so brought within the range of Christianizing and civilizing ideas, in the largest sense. All existing missionary work is trivial as compared with this. For your system would throw wide open those vast countries, as, indeed, all the countries of the world, to the whole current of English and American thought."

For Diffusion of English throughout the World

THE UNIVERSAL LANGUAGE

This "Hand-Book of World-English" is the Complete, Simple, and Efficient Medium.

FOREIGNERS

Will Acquire, by Means of this Hand-Book, a PERFECT PRONUNCIATION OF ENGLISH.

For Primary School Pupils and Illiterate Adults

World-English is a Royal Road to Reading.

To Teachers of English and Modern Languages

This Hand-Book will be of Primary Importance as a Phonetic Directory.

DEFECTS OF SPEECH

Will be Readily Corrected by Means of the Articulate Directives in this Hand-Book.

HAND-BOOK OF WORLD-ENGLISH,

25 CENTS.

The plan of this little book is altogether new. Letters and sounds are so associated, in all the exercises, that from the mere knowledge of letters a learner cannot fail to pronounce words with certainty. English reading will thus be easily acquired, whether by natives or foreigners, children or adults.

The general resemblance of World-English to Literary English is such that any reader of the latter deciphers the former at sight, or, at most, after a few minutes' study of the new letters. A like result may be anticipated for those who shall learn to read from World-English. They will transfer their power of reading to the literary form of the language, almost without effort. The orthographic aspect of words will, besides, be so fixed in the eye, by contrast, that spelling will be remembered as — what it really is — a pictorial association with words.

No special training is required to qualify teachers for using this book. The subject can even be successfully introduced in the kindergarten and the nursery. This phonetic mode of initiation in reading cannot be too strongly urged on the attention of School Boards on both sides of the Atlantic.

The ordinary orthography of each word is interlined with the World-English version throughout the Exercises and Readings.

So set down, our tongue is the best for the world to unite upon. — *Brooklyn Eagle*.

The idea of Mr. Bell has much to recommend it, and the presentation is charmingly clear. — *American*, Phila.

The result is a language which cannot fail to meet with acceptance. — *Boston Traveller*.

Has the merit of great ingenuity. — *Railway Age*.

His treatise, as a study of English orthoepy, condenses the result of much thought and experience in small compass. — *The Critic*.

World-English is the English language unburdened of its chaotic spelling. — *Popular Science Monthly*.

We commend it to the attention of teachers. — *Ottawa Globe*.

"World-English" and "Hand-Book of World-English" can be had of all booksellers, or will be sent for 50 cents, post free, by the publisher,

THE GREAT FALLS, ON THE PASSAIC RIVER, IN PATERSON, N.J., 15 MILES FROM NEW YORK, SHOWING WASTE OF WATER INTO THE SEA. [See p. 203.]

THE WATER PROBLEM OF NEW YORK.

THE water problem before the city of New York, how to meet the increasing demands of the vast and fast-growing population for water for domestic use, sanitary purposes, and for the requirements of commerce and manufacture, has been answered by Mr. John R. Bartlett. While engineers and politicians have been speculating with the limited possibilities of the Croton watershed, and with visionary plans for diverting the waters of the upper Ramapo River, and for getting an additional supply from the Adirondacks or Lake Erie, and have reduced to despair sanitarians and all others acquainted with the really critical condition of the city's affairs on the water question, Mr. Bartlett has been quietly maturing plans which meet the emergency practically and conclusively. He offers to furnish the city with not less than 50,000,000 gallons of pure water daily, under a head pressure of three hundred feet. He and associates have the water to sell, the unquestioned right to sell it, and will pour it into the city ready for use without demanding of the city a single dollar before the water has been delivered.

These plans have been recently presented to the sinking-fund commissioners of the city, and are elaborately set forth in a folio volume of a hundred and seventeen pages. The water is to come from the Passaic watershed, situated in the States of New Jersey and New York; and the quantity supplied to New York City will not more than equal the amount of rainfall in that portion of the watershed which lies in New York State. In the book is discussed every phase of the problem. It anticipates every question which the extent of the plans suggests, and abounds in statistics and comparative calculations which show deep research, and will be valuable for reference for all cities.

In order to properly appreciate the magnitude and the beneficence of this project, an outline of its inception and progress is necessary. The data which follow are furnished by Mr. Bartlett's book and the recent well-known history of New Jersey. They tell a story of successful enterprise, on whose completion the State of New Jersey and the entire metropolitan district are to be profoundly congratulated.

Mr. Bartlett first directed his attention to the crying demand for pure water raised by the cities and towns east of the Orange Mountains in New Jersey. Newark and Jersey City, the chief municipal centres of this region, and incidentally the suburban and adjacent towns, had been agitating the question for years. Official inquiries of engineers and health-officers instituted by these plans had evoked on each occasion the startling result that the water furnished their people was unfit for use, and was a constant menace to the health of the communities. The various examinations showed a steadily increasing danger. This was made manifestly logical and necessary by the fact that the water for this region was taken from the lower Passaic River, a tidal stream, and at a point in the river where the pollution from the fast-growing cities and increasing factories was all deposited.

The only remedy lay in getting water from a source above the point of pollution. The State was manifestly helpless, because of its inability to legislate to any particular locality rights to which all places had a just claim; nor could it attempt a general relief, because of the immense amount of money which would be required to pay for the condemned land and the taking-away of individual rights. Even if this should be accomplished by a vote of the people of the State, other serious constitutional objections interposed, and difficulties of a practical and business nature which were well-nigh insurmountable. The helplessness of the cities themselves was even more pronounced, as added to the State's difficulties were individual indebtedness and political imbroglions, which have been fully ventilated during the last year.

A unification of all interests was essential,—a harmony of action on the part of all the water companies and corporations having rights below the point designed for the source of supply, a similar harmony of all riparian owners, and a harmony of all legal rights to the water,—in fact, a condition was essential which seemed beyond the reasonable power of human energy to bring about, and this is the condition which Mr. Bartlett has successfully worked out.

The detailed story of how the history of this entire section, from

its original granting to the present time, was mastered, in order to ascertain beyond peradventure the absolute rights of every claimant; how the records of judicial action during this time were all consulted to justify these rights; how the engineering problems, as many as anticipation of any diverse plans might ever involve, were all solved; how the legal aspect of every phase of the work was fully understood at each step; how the immense business manipulations of purchasing the many acres of property and satisfying all owners were accomplished,—how all these things were done will be an interesting chapter of a future history of New Jersey. Suffice it here to note with amazement and pride that it all has been done.

The immense Passaic watershed of the States of New Jersey and New York was at command, and the water was ready to be poured into the houses of the long-suffering people. Here developed the most interesting phase of the project. The extent of the watershed is about 877 square miles. The average daily capacity is 700,000,000 gallons. A computation based on the most generous allowances, and in accordance with the well-known increasing demands for water by each succeeding generation, showed that the State of New Jersey could not within any time that fair calculation could devise, certainly not within a hundred years, use, or waste in generous use, more than 300,000,000 gallons daily. The remainder, 400,000,000 gallons, would continue as now to flow away into the sea. To devote to practical use this immense amount of water was a problem which immediately arose. The condition of New York City and its fast-increasing water wants suggested at once a proper place to bestow it. Here the Croton watershed was being taxed to its utmost capacity. Aside from the danger to a great city like New York of depending on only one source of supply for water,—a danger which all great municipalities recognize and guard against to the utmost limit,—this source was showing evidence of soon becoming insufficient to supply the requisite amount of water. Its whole capacity, with Quaker Bridge dam and every other storing contrivance utilized, would be only 250,000,000 gallons daily. To estimate the future by the records of the past, within ten years the wants of the people of New York City could not be supplied.

The dependence on a bountiful supply of water of a city's progress and welfare is so well known that it need not be argued. It is an axiom. In small towns, where the chief consumption is confined to the direct uses of the inhabitants, the amount of water used *per capita* can be small; but in a large municipality people are not the only consumers. The onward march of steam, and the various succeeding inventions of civilization, have rendered necessary an immense amount of water for their assistance. Large cities, therefore, have this quantity included in the *per capita* use of water; and, besides the other considerations of better health and greater security, a larger *per capita* use of water indicates an advanced state of prosperity. A ridiculous argument has been used in New York against increasing the water-supply. "Let the waste of water be stopped," it said: "we are using too much." The fact is, that a generous use of water could not be indulged without a generous waste. The permanent necessity of the former renders the latter not an evil, but a desirable condition. Moreover, statistics show that the ratio of increase of population does not in any degree determine the ratio of increase in the water wants of a city; because, whereas in a small community 10 gallons daily *per capita* might be sufficient, in a large community the various other uses of water mentioned above would render the *per capita* needs considerably over 50 gallons.

A striking illustration is furnished by the city of Philadelphia, where in 1810 they used 7 gallons of water *per capita*; in 1830, 17 gallons; in 1860, 36 gallons; in 1880, 68 gallons; in 1886, 80 gallons; and it is said the figures of this year will show 100 gallons.

These facts serve to show more conclusively the imminent necessity for immediate attention to New York's wants. Mr. Bartlett's efforts had brought an available quantity of water from a pure source to the opposite banks of the Hudson, where he was confronted with a new series of problems, legal and mechanical. He meets all the questions as to the right to bring the water through and out of the State of New Jersey with opinions giving specific

and unqualified indorsement from ex-Chancellor Benjamin Williamson, ex-Gov. J. D. Bedle, ex-Gov. Leon Abbett, Henry C. Pitney, Garret A. Hobart, A. Q. Keasbey, William Pennington, Henry C. Andrews, ex-Chancellor Theodore Runyon, Barker Gummere, and decisions of the courts of last resort of both States. Thus arrayed, is the best legal talent in New Jersey.

The formidable task of crossing the Hudson with absolute confidence, he also solved, and in a most remarkable manner. Instead of presuming on a plausible theory, many of which abound, Mr. Bartlett set to work on the best theory, and worked it out at a cost of nearly \$200,000. This was done for the purpose of ascertaining whether a certain opinion he held was correct or not. His opinion was that the Hudson River Tunnel, at that time practically aban-

tion of the city government. Upon receipt of the report, the board passed a resolution authorizing the committee "to recommend Mr. Bartlett's proposition to the favorable consideration of the commissioners of the sinking-fund, and urge upon them the adoption by the city of the proposition in accordance with the plans submitted, in order to secure to the city an adequate supply of water for all purposes, and to meet its present needs, and that the same be done as promptly as possible."

A board of engineers, composed of Clemens Herschel, A. Fteley, and Capt. T. W. Symons, U.S.A., carefully examined the plans of Mr. Bartlett, and made a report as follows: "We do recommend as an entirely practicable and valuable project the general plan which has been submitted by you for supplying a portion of New

RAMAPO RIVER IN ORANGE COUNTY, N. Y., SHOWING THE VOLUME OF WATER FLOWING INTO NEW JERSEY.

done, could be made to serve the purpose of holding the conduits, the great water-mains. In this way he built a large section of the tunnel from the New Jersey end, and the fact was thoroughly demonstrated that the rest could be built the same way; and that the water-way was secure.

Accompanying the proposition of Mr. Bartlett and his associates is an indorsement, confirming all that Mr. Bartlett says of his project and its possibilities, by all the companies or societies which have any controlling water-rights below the point of diversion in the State. These are the Society for Establishing Useful Manufactures, the Lehigh Valley Railroad Company, the Dundee Water Power and Land Company, the Acquackanonk Water Company, the West Milford Storage Company, and the Montclair Water Company.

A committee appointed by the New York Board of Fire Underwriters to examine into the merits of Mr. Bartlett's plan reported that in their judgment the plan was feasible, and, if adopted, would be of great benefit to the city, and was entitled to the support and indorsement of the underwriters, and to the favorable considera-

tion of the city government. Upon receipt of the report, the board passed a resolution authorizing the committee "to recommend Mr. Bartlett's proposition to the favorable consideration of the commissioners of the sinking-fund, and urge upon them the adoption by the city of the proposition in accordance with the plans submitted, in order to secure to the city an adequate supply of water for all purposes, and to meet its present needs, and that the same be done as promptly as possible."

York City from the drainage area of that part of the Passaic watershed that lies in the State of New York, and in the manner herein described, including the use of a tunnel under the Hudson River for carrying the necessary water-conduits across the river in a safe, durable, and trustworthy manner. We summarize its principal advantages as follows: 1. It will furnish to the city of New York an independent supply of water from a new and independent source and by a new and independent route; 2. This supply will be delivered directly into those portions of the city most remote from the present source, and where the pressure is most inadequate; 3. It can be delivered under any pressure desired, up to three hundred and fifty feet of head, and supply all high buildings and districts without pumping, thus resulting in a great saving to individuals; 4. It will furnish most perfect fire protection, and consequently greatly reduce the cost of insurance."

A memorial of fire-underwriters to the commissioners of the sinking-fund of New York, upon this subject, signed by the officers of all the fire-insurance companies in the city, concludes as follows:—

"The proposed method of projecting water upon fires would greatly reduce the cost of that service as administered at present, and at the same time vastly add to the efficiency of the means of extinguishing by the application of water. First, it would enable a few men with a light hose-carriage to reach the point of fire much quicker than the present heavy engines to-day; and at the breaking-out of a fire a minute is sometimes worth a million dollars, and frequently a hundred thousand. Second, it would enable the firemen, by the use of permanent stand-pipes, to connect short lengths of hose, and apply the water in large streams and solid masses; whereas at present, even when two or three engines are forcing water through a single pipe, or tower, the stream is largely converted into spray before it reaches the fire, and is then converted into steam, and even into a gas that aids combustion rather than stops it."

The medical authorities and health-officers of this city have given this plan much careful consideration, and their conclusions are favorable to the project. Mr. James C. Bayles, president of the Board of Health, in a communication to Mr. Bartlett, gives his views as follows:—

"It is undoubtedly true that at the present time large portions of New York are very inadequately supplied with water. This department has constant and serious trouble in that branch of its work which deals with the plans of tenement-houses and other dwellings, owing to the fact that the available supply of water is in many cases so small as to forbid a proper cleansing of plumbing fixtures, if these are provided. There are large districts of the city where the pressure rarely carries the water above the first story; and in the case of tenement-houses, divided into many apartments, each apartment must be provided with one or more pumps, which, finding their supply from the three-fourths-inch tap at the street-main, are not always able to lift the water required for domestic use. A good water-supply, abundant in quantity and excellent in quality, is a condition precedent to the healthfulness of a community. This is especially true of a crowded community like New York. I am of the opinion that no one thing would do so much to facilitate and make effectual the work of this department as a great and immediate increase in the water-supply, under pressure sufficient to reach the upper stories.

"I am unable to favor, from a sanitary point of view, the measures which have been suggested, looking to a restriction of consumption in order to prevent the present admitted large waste. A liberal use of water accomplishes what can be attained in no other way,—the cleansing of pipes and sewers; and people who have access to all the water they desire and can use, are likely to be cleaner in their homes and persons than those who suffer restrictions in this most important item of daily consumption. I do not think the sanitary aspects of the question with which we are now confronted, growing out of an admitted scarcity of water in New York, can be exaggerated.

"An increased supply and better distribution of water in New York would undoubtedly tend to diminish the number of contagious and infectious diseases with which we now have to deal, and would produce a marked improvement in the public health. If it were not for its peculiar position as the gateway of this continent, to which more than eighty per cent of the inflowing travel and immigration tends, our death-rate would not be so large as it is. For example: if the deaths among immigrants who have never become a part of our population could be eliminated from our totals, we should last year have reduced the death-rate per thousand from twenty-four or twenty-five to twenty-two. If, further, we could avoid the overcrowding of Italian and other impoverished immigrants in our tenement-house districts, our death-rate would compare favorably with that of the most healthful city of the world.

"It will not do, however, to attach too much importance to these hopeful figures. They are liable at any time to be changed, and nothing will tend so quickly and effectually to change them as a failure in the water-supply of the city. Of the dangers to which this is subjected, I do not need to tell you.

"Answering your question with reference to the effect which an increased water-supply would have in diminishing the number of malignant diseases of a contagious or infectious type, I regret that I am unable to be specific. This, of course, is largely a matter of

opinion, but it is an interesting fact that a very large proportion of the cases of contagious and infectious disease which come under the care of the Board of Health are taken from the upper floors of tenement-houses. Whether this is due to lack of water, which is greatest on the upper floors, or to impurities in the water which rise to about that level, I am unable to say. I believe, however, that a material increase of the city's water-supply would promptly and permanently reduce the public burdens entailed in the care of the city's sick.

"The cordial sympathy and co-operation of this department would be extended to any practicable scheme looking to a supply of water for New York from other sources than the Croton watershed. Our city is growing with great rapidity, especially in the 23d and 24th wards, north of the Harlem River. It is probable that the needs of this district will not be more than met by the increased supply to be obtained through the new aqueduct, when all the engineering work looking to the impounding of additional water is completed."

If more need be said upon the subject from a sanitary standpoint, it is furnished by the following preambles and resolutions adopted by the Medical Society of the State of New York at a meeting held Sept. 24, 1888:—

"Whereas the present scarcity of water in this city is causing great inconvenience as well as serious apprehension for sanitary and other reasons; and

"Whereas the new aqueduct will not materially increase the present supply from the Croton watershed until after the storage-reservoirs are completed, six or more years from now; and

"Whereas the upper portion of the city, with its rapidly growing population, will soon require all the water that can be procured from that source; and

"Whereas the present insufficient supply of water is a constant menace to the health and safety of the city, inviting scarlet-fever, diphtheria, cholera, and other malignant diseases, as well as disastrous conflagrations: therefore be it

"Resolved that this society has listened to the explanation of the plans proposed by John R. Bartlett, Esq., for furnishing the city of New York with an additional supply of pure water, from a source independent of the Croton watershed, and that it approves the same, and urgently recommends it to the attention of the city authorities having such matters in charge."

PRUNES IN FRANCE.

THE introduction of prunes into France is attributed to the Crusaders, says our consul at Bordeaux; and, if tradition is exact, this valuable fruit was first cultivated in the south-west of France by the inmates of a convent near Clairac. In travelling from Avignon to Fumel, through the valley of the Lot, fertile plains are seen covered with plum-trees, which furnish the famous *prunes d'Ente* and *Robe-Sergent*, these being exported to the remotest corner of the commercial world. The plum-tree does not confine itself to this particular district of France, but it is profitably cultivated in the valley of the Loire, the departments of the Garonne, Dordogne, Tarn, and Aveyron. The well-known brand called 'Tours' prunes comes from the orchards of the Loire. Lorraine produces a variety called *Quetsche*, one of the best for ordinary preserves.

The prune-tree thrives best in clayey, calcareous soil, and does not exact for its roots a loam of profound depth. Land adapted to the culture of the vine is also partial to this tree. In many localities these two valuable products are cultivated together, as the broad leaf of the vine is especially useful in protecting the roots of the tree from the intense heat of summer. When the prune is ripe, it is covered with a sort of glaucous powder called "flower," which greatly adds to its value as a table-fruit. The fruit is usually gathered after the heat of the day has dissipated the humidity of the night, and, when possible, straw is spread beneath the trees to prevent the fruit coming in contact with the earth. Only such fruit as readily falls when the tree is slightly shaken is gathered. As soon as harvested, the fruit is taken to a building, where it remains for a few days to complete maturity.

Prunes are subjected to not less than three, and frequently to four, distinct cookings before being pronounced ready for market.

The first two preliminary cookings have for their object the evaporation of water contained in the fruit, and preparation for the final cooking, which dries the fruit and imparts a certain brilliancy much sought after by buyers. In several districts of France, most primitive means are practised in curing the fruit for market. In Provence freshly gathered fruit is plunged into pots of boiling water, where it remains until the water again arrives at boiling-point. It is then removed from the boilers, placed in baskets, and gently shaken until cool, when it is placed on long trays and exposed to the heat of the sun to complete desiccation. At Digne the prunes are not gathered until completely matured. Women peel the fruit

and cumbersome, and very primitive in their construction, only consisting of a frame to which is fastened a wicker-like bottom fashioned from rushes or willow twigs. They hold from twelve to eighteen pounds of green fruit, representing about four to six pounds of prunes. Care is taken, in preparing the oven for the first cooking, that the degrees of heat shall not exceed 50° C.; and in the second, 70° .

After each cooking, which occupies about six hours, the fruit is removed from the oven and exposed to the air. When the prunes are cold, they are carefully turned by women specially charged with this duty. They avoid disturbing the fruit while it is warm, as the

THE ROCKWAY RIVER AT THE BOONTON FALLS, SHOWING INTAKE OF THE MORRIS CANAL (ELEVATION ABOVE TIDE-WATER ABOUT 565 FEET).

with their nails to avoid injury to the soft pulp. The fruit is strung upon small twigs, and in such fashion as not to touch. These sticks of prunes are stuck into straw frames, which are suspended in the sun until the prunes easily detach themselves from the stick. The pit is then removed, the fruit placed upon trays exposed to the sun, and, when thoroughly desiccated, packed for market. In the departments of Indre-et-Loire and Lot-et-Garonne, immense ovens, specially constructed for prune-cooking, are used.

Most prunes are subjected to a preliminary washing to free them from dust or sand. After washing, the fruit is exposed to the sun or air on beds of straw, or on the trays on which it is cooked, to rid it of all humidity. When dry, it is spread in a single layer on the tray, and at once submitted to the oven. The trays used are made during the winter months by peasants. They are clumsy

touch renders it glutinous and prevents the fruit from congealing. The third cooking is performed at a temperature of 80° to 90° , and occasionally at 100° . After the third cooking, the prunes are sorted, and such as are found imperfectly cooked are again submitted to the oven. The degree of perfection in cooking is obtained when the fruit presents a dark purple color, solid and brilliant surface, malleable and elastic to the touch, and when the kernel is well done and intact in the shell. When these conditions are not obtained, the kernel ferments, and alters the entire prune, which very soon becomes mouldy and worthless.

Prunes are divided into nine categories, and are classified as follows: No. 1 represents 90 to 92 to the pound; No. 2, 80 to 82; No. 3, 70 to 72; No. 4, 60 to 62; No. 5, 55 to 56; No. 6, 44 to 45; No. 7, 40 to 41; No. 8, 34 to 35; and No. 9, 30 to 31. When ready

for exportation, the fruit is pressed flat between two cylinders covered with India-rubber, and then packed into cases by a special machine, called a "packer." Many dealers still perform this operation in the primitive manner of foot-pressure. Bordeaux is the principal centre of their industry, which is yearly increasing.

Besides the large amount of prunes exported to European countries by rail, there are, says Consul Roosevelt, about one hundred vessels annually leaving the port of Bordeaux loaded with this produce. In the beginning of the prune-industry, many devices were employed for their proper conservation. The first ovens were very primitive, and the work of preparing the fruit for market laborious. At present there are many different kinds of ovens in use, possessing more or less distinct features, but almost the same in general principles. The most generally used are the Bournel and

We also give a view taken from a photo of the Asheville, N.C., Electric Railway.

Asheville is a flourishing mountain town, noted throughout this country as a health-resort; and it is characteristic of such a town and its enterprise that it now has an electric railway, first-class in all particulars, which gives the people perfect and comfortable means of transit to the depots and hotels, and replaces the old springless hacks and primitive omnibuses.

The picture shown is from a photo taken shortly after the opening of the road, and represents three of the Sprague electric cars turning a corner into the main street of Asheville, N.C.; and it is an interesting feature to notice that it is difficult to discern the overhead system at all, on account of the smallness of the wires.

Besides an equipment of passenger street-cars, this electric rail-

the Marletean ovens. The only ovens in use are of French manufacture.

SOME NEW ELECTRIC RAILWAYS.

THE accompanying engraving is from a photograph representing one of the Sprague electric cars in operation at Steubenville, O., passing under a railroad-bridge on the route of the road. The picture gives a very good idea of the wide range of movement of the trolley-arm, which can reach from 12 to 14 feet above the car, to less than 1 foot, when the location of overhead wire demands such a wide change. The kind of trolley-pole used upon this road is light and unobtrusive, consisting of a light, hollow iron rod carried on top of the car, and supported from the car by a stout steel spring, which allows it to move in every direction necessary.

The equipment of this road includes the regular Sprague system of overhead wiring, with main and working conductor running parallel, connected at intervals of every 100 to 200 feet. The road has been a success from the start, and has been visited by many street-railway managers from Ohio, Indiana, Kentucky, and western Pennsylvania.

way also possesses several freight-cars, also operated by electric motors of the Sprague type; and, as this road connects the depot of the North Carolina Railroad with the city of Asheville, these freight-cars have proved a convenience and a source of income.

THE SUBMARINE BOAT "GYMNOTE."

WE have already given some details of the "Gymnote;" but the following, taken from *Industries*, gives some additional information as to her construction. After the first trials of the "Gymnote," it was found that various details required modification, but on the whole the trials were satisfactory; and, now that the improvements which the first trials indicated to be necessary have been made, the French Government have accepted the "Gymnote" as the standard type of submarine vessel for offensive purposes. The hull is spindle-shaped, 6 feet in diameter by 56 feet long, provided with horizontal and vertical rudders, and with a cylindrical conning-tower of somewhat novel design. The conning-tower consists of a fixed tube, within which slides a second tube, carrying at its upper end a mirror inclined at an angle of forty-five de-

grees. When the inner tube is pushed right out, and the boat is floating near the surface, only the top of the telescope tube need be above the water; and the captain, standing within the boat, by glancing upward, can see in the mirror what is going on in front of him, or, for the matter of that, all around him, if the inner tube be revolved. By means of this ingenious application of a telescopic conning-tower with a mirror, the size of that part of the vessel which must project above the water-level to permit of an observation being taken, has been much reduced, as compared with the old plan of making the conning-tower large enough for the captain's head and shoulders to enter. In the stem of the vessel is fixed the torpedo-launching tube, and in the stern the electric motor by which the propeller is driven. There are various water-ballast tanks by which the vessel is trimmed, and access to the in-

distance that the boat could travel with one charge would be about 120 knots.

While the "Gymnote" is a boat mainly intended for the discharge of torpedoes against the enemy's ships, a second and much smaller submarine boat is now being built, the mission of which will be to render the enemy's submarine mines harmless by cutting their cables. This boat is also spindle-shaped, but only 15 feet long by 5 feet 3 inches in diameter, and will have a crew of two men only, whereas the crew of the "Gymnote" is from six to eight men. As the cubic capacity of this boat is comparatively small, compressed oxygen is to be carried as part of the equipment. The boat is to be provided with powerful scissors, working from inside, by means of which it is intended to cut the electric cables of the submarine mines. The screw is mounted on a swivel-shaft to fa-

VIEW OF ELECTRIC ROAD AT ASHEVILLE, N.C.

terior is afforded by a man-hole a little forward of the conning-tower. The power for working this vessel is derived from a battery of 564 Commelin & Demazures alkaline accumulators, weighing, in working order, close upon 10 tons. A compound switch is provided by means of which the battery can be differently grouped; the combinations being 12 cells parallel and 47 in series for very slow speed, 6 in parallel and 94 in series for slow speed, 4 parallel and 141 in series for ordinary travelling speed, and 2 parallel and 282 in series for fast speed. The weight of the battery per horse-power is 83 pounds. The electric motor works the propeller direct without the intervention of any speed-reducing gear, and has been specially designed for this purpose by Capt. Krebs. It is a sixteen-pole disk machine, weighing 2 tons, and developing 52 horse-power at a speed of only 280 revolutions a minute. The armature is 40 inches in diameter, and the winding is such as to require only four brushes. The resistance of the machine is .16 of an ohm. At full speed, the motor is sufficiently powerful to propel the boat at a speed of 9 to 10 knots per hour; the capacity of the battery being said to correspond, under this condition, to about four and a half hours of work, which would take the boat over a total distance of 40 to 45 knots. At a speed of 6 knots an hour, the total

cillitate the manœuvring, and is worked by an electric motor driven by a battery of Schanscheiff primary cells. The boat is lighted by five small glow-lamps; and a small arc-lamp with a projector is also provided, the beams of light from which can be thrown forward through glass lenses fixed in the hull, so as to illuminate the water for a certain distance ahead, and thus make the work possible for which this boat is especially intended.

If this country is going to rely to a great extent on torpedoes as a coast defence, the recent improvements in submarine boats cannot but be of great interest to Americans. Congress recently appropriated a considerable sum for the construction of such a vessel, and, although nothing definite is known about the plans that will be adopted, yet it is understood that electricity will not be the motive power.

NATURAL GAS IN OHIO IN 1888.

A LATE number of the *American Manufacturer* has a careful review of the natural-gas situation in Ohio, by Professor Edward Orton, the State geologist, who says in effect that no important discoveries have been made in Ohio during the year 1888, though a

great deal of drilling has been going forward, and the productive districts remain as at the end of 1887, four in number; viz., the Berea grit, the Ohio shale, the Clinton limestone, and the Trenton limestone. The last-named stratum, which is both a gas and oil bearing rock in northern Ohio and central Indiana, is, excepting possibly the Bradford sand, the most important single source of petroleum and gas on this continent. The oil is still ranked as inferior, on account of the present difficulty of refining it; but there is no drawback to the gas, as is apparent from the following analyses, made for the United States Geological Survey:—

	Findlay.	Postoria.	St. Mary's.
Hydrogen.....	1.64	1.89	1.74
Marsh-gas.....	93.35	92.84	93.85
Olefiant gas.....	.35	.20	.20
Carbonic oxide.....	.44	.55	.44
Carbonic acid.....	.25	.20	.23
Oxygen.....	.39	.35	.35
Nitrogen.....	3.45	3.82	2.98
Sulphuretted hydrogen.....	.20	.15	.21
Total.....	100.00	100.00	100.00

The small fraction, one-fifth of one per cent, of sulphuretted hydrogen is held to be decidedly advantageous, as it affords a certain means of detecting leaks.

No place within the natural-gas belt has derived greater advantages from this fuel-supply than Findlay, where in November, 1884, it was first found that the Trenton limestone, at some places at least, contained stores of high-pressure gas. Since January, 1886, the population of the town has increased from 6,000 to 30,000. Although there are rolling-mills, chain-works, machine and edge-tool shops, etc., the principal industry is glass, 155 pots being used by the ten firms engaged in making window-glass, fine flint ware, and bottles.

This growth has been built up in Findlay, as in other towns, by giving free, or nearly free, gas to manufacturers, — a gift which in some instances has been supplemented by land and contributions to capital, either from the town or parties interested in real estate. Under these circumstances, the question of the continuance of the supply is a vital one. Professor Orton has contended that the supply is a stored one, and notwithstanding the reasonableness of the theory, in view of the exhaustion of all deposits of liquid hydrocarbons, the gas has been used most profusely for the rough work of founderies, rolling-mills, brick and tile works, lime-burning, and the like, until, a short time since, Findlay found itself short of gas. A new well was drilled in, and, on being shot, responded with a pressure in the open casing of from 38 to 40 pounds, equivalent to a yield of about 30,000,000 cubic feet per day. The famous Karg well, which has been the main reliance of the town for the past two years, was estimated to discharge 12,000,000 cubic feet.

This shortage of gas has led to an investigation, from which the professor concludes that none of the large wells in the field have flowed three years, practically unrestrained, without giving unmistakable signs of nearing their limit. In some cases oil invades them; in others, salt water. The smaller wells appear in some instances to have a longer lease of life than the great wells. In some of the town wells the original rock pressure has been reduced by about three-eighths, but in others it is claimed it is fully maintained, only more time is required for gathering. The area exhausted by a vigorous well is not yet determined, but it is thought that the central portion of Findlay is partially drained of its original supply. As the city has pledged itself to furnish many million feet of gas each day, great energy and sagacity will be required to maintain in full vigor the splendid industries now established, and insure the continued prosperity of the town.

What is predicted of the Ohio Trenton limestone gas-field may probably be asserted as to the 2,000 square miles of the field in Indiana, though, if wells yielding 30,000,000 cubic feet of gas per

day, equivalent to nearly 1,000 tons of coal, are to be found whenever a shortage occurs, there may be a longer lease of the industrial life of that region than a cursory reading of Professor Orton's article might lead one to infer.

THE DENISON MOTOR AND DYNAMO.

THE accompanying illustration shows the form of dynamo and motor now manufactured by Mr. J. F. Denison of New Haven, Conn. These machines do not differ in their construction much from that which experience has shown to be desirable, but the motors have some points worthy of special consideration.

An arrangement known as the Denison interlocking starting attachment is contained in the base of the machine, and is said to prevent any mistake in operating the motors. This attachment is

THE DENISON MOTOR AND DYNAMO.

so arranged that the current cannot be thrown on unless the resistance in the rheostat in the base is in the proper position. This is manipulated by a hand-wheel. In case of accidental breaking of the circuit, an automatic lock makes it impossible to turn the current on until the resistance is again in normal condition. The absence of attachments external to the machine, which are usually placed on the wall, the machine being entirely self-contained, does away with the expense of sending out special attendants to set it up. Further, as there are but two binding-posts, it is impossible to make a mistake in wiring.

HEALTH MATTERS.

Analysis of Foods.

THE commissioner of internal revenue of the United States has published the regulations concerning the analysis of foods and drugs in the District of Columbia. These regulations are based on the Act of Congress passed in 1888, entitled "An Act to prevent the Manufacture or Sale of Adulterated Food or Drugs in the District of Columbia." Section 12 of this Act provides that any health-officer, inspector of nuisances, or any food-inspector, may procure any sample of food or drug, and, if he suspects the same to have been sold to him contrary to any provision of the Act, he shall submit it to the commissioner of internal revenue to be analyzed. An offence shall be deemed to be committed in the case of drugs, if it differs from the standard of strength, quality, or purity laid down in the pharmacopœia, or falls below the professed standard under which it is sold. In the case of foods, the regulation gives a standard for butter, cheese, cocoa, chocolate, coffee, honey, lard, malt liquors, milk, mustard, olive-oil, oysters, pepper, tea, vinegar, wheat flour, bread, and wine.

A large number of coloring-matters are prohibited for use in foods. Among these are aniline, gamboge, fuchsine, naphthol yel-

low, and others. Salicylic acid and its salts are prohibited, as are also boracic acid and borax, glycerine, and alum. A list of harmless coloring-matters is given. The pamphlet also contains a list of periodicals, official reports, and general and monograph volumes of the greatest importance in connection with the detection of adulteration of food and drugs. This bibliography is exceedingly valuable, and, we should judge, very complete.

THE SURGEON-GENERAL AND THE NATIONAL BOARD OF HEALTH.—The "Annual Report of the Supervising Surgeon-General of the Marine Hospital Service of the United States for the Fiscal Year 1888," has just been published. It contains the customary statistics of this branch of the national service, and, in addition, a considerable amount of interesting matter in reference to the recent epidemic of yellow-fever in Florida, with photographic illustrations of the camps of refuge, and a map of Jacksonville showing the streets and sewers. It is much to be regretted that the supervising surgeon-general should, in an official report, have attacked the National Board of Health, and the excellent work which it did during the days when it had the power and the means. He charges Dr. Bowditch of Boston with "special pleading for a pet object," when, in September last, he expressed in a public letter the wish that a new birth might be granted to the national board with greater powers. The supervising surgeon-general speaks of this letter as being "ingeniously constructed," and further says that unfortunately the facts do not bear out the statements therein contained. If men of the standing and reputation of Dr. Bowditch can be thus attacked in governmental reports, we shall wish that some censorship may be established to which these reports shall be submitted before they are permitted to go forth with the official sanction.

TEMPERANCE INSTRUCTION IN PUBLIC SCHOOLS.—The report of the Department of Scientific Temperance Instruction in Public Schools for the year 1888 shows that twelve million children in this country are now under compulsory temperance education laws; that is to say, that the law has provided the education in favor of total abstinence that results from learning the nature and effects of alcoholic drinks and narcotics. This report further shows that there is no New England State without such a law; New Jersey is the only Middle State that has not enacted such a law; ten Southern and two Western States are still unprovided in that regard. The Act of Congress of 1886 brought all the Territories under the law. Those interested in this subject will find reports from the different sections of the country of the work done, and the difficulties to be met and overcome in States in which as yet compulsory laws have not been enacted.

DIPHThERIA AND SANITATION.—If the reports which the newspapers publish in reference to the sanitary condition of Gallitzin, Penn., are true, it is not a matter of surprise that diphtheria, once introduced, should prevail in epidemic form. In a population of only two thousand people, one hundred deaths from this disease are said to have occurred since November. The disease is attributed to the disregard of the common rules of sanitation. The town has no water-supply. The outhouses and wells stand close together, and, since the McCoy mines have been opened, over half the wells in the town have gone dry. The inhabitants have used water from the few remaining wells that have become impure. Fortunately there is an excellent State board of health in Pennsylvania, which will at once take the matter in hand.

ETHNOLOGY.

The Blackfoot Sun-Dance.

MUCH has been said regarding the barbarous dances of the Blackfeet and their neighbors, but the majority of reports have been made on hearsay. Therefore an authentic description of the ceremonies by an eye-witness, who is, moreover, thoroughly conversant with the native language, must be highly welcome to students of primitive man. The Rev. Dr. John McLean has presented such a description to the Canadian Institute of Toronto. It is one of the important results of the establishment by the British Association, of a committee for the study of the Indians of the Canadian

North-west, that missionaries begin to improve their opportunities of observing native customs, and of making available their studies of native languages.

The sun-dance is celebrated every summer. Last summer, when Dr. McLean visited the Blood Indian camp, he found the sun-lodge erected. There were by actual count one hundred and ninety-eight lodges, comprising about two thousand souls. An old man was riding through the camp, calling upon the people to attend the ceremonies. In a lodge near at hand, a medicine-man was decorating the persons who were to undergo the rite of torture. In arranging their head-dress, before putting it on, he passed his hand around it four times, praying. In the sun-lodge the sacred fire was burning, and this was used by the people for lighting their pipes. No child or woman was allowed to supply the fuel; but young men who had performed some valorous deed, especially the stealing of horses from a hostile tribe, felt it to be an honor to attend to this duty; and none but the brave are qualified for this work. On the sacred pole were placed, in the form of a cross, two bundles of small brushwood taken from the birch-tree. The pole was decorated with sacrifices to the sun of clothing and various kinds of Indian goods. The cross evidently refers to the four winds, from its four points, as does the number 4, which is regarded as the sacred number. In the bower made of light brushwood sat a woman who gave the festival that year, her husband, and a medicine-man. These persons were fasting and praying; and, during the full term of the continuance of the ceremonies, very little food was partaken of. In the mornings they were allowed a short smoke and a little water; and in the evenings a few of their friends brought a small quantity of food hidden under their blankets, and, without exposing it to view, it was eaten in silence. The medicine-man had a crown of leaves upon his head. His body was painted, and without any clothing, save a long strip around his loins. At short intervals he arose and danced, keeping time to the motions of his body with a small bone whistle, which he blew upon incessantly, producing a series of monotonous sounds. In the evening the woman prayed to the sun for good health for the people, protection in danger, good crops, and a bountiful harvest of wild fruits. The virgins came in the evening, and prayed for a long time for blessings from the sun. During the day the ceremonies consisted of dramatic representations of heroic adventures by single individuals, and contests with the Crow and Sioux Indians by war-parties. One chief borrowed several guns from his friends, and a large number of Indian war-instruments and native trinkets. Stepping forward that all the people might see him, amid profound silence, he addressed the assemblage. Holding a gun aloft, he told how, in a contest with an enemy, he had slain him and taken his gun. The band of musicians beat on their tomtoms in token of applause. Each article that he had represented his various victories, and each had its separate story, which was narrated at first, and the same routine gone through. When he had finished, the whole assemblage joined the musicians in applauding the speaker. Many warriors during the day related their brave deeds in the same manner.

Sham-fights were engaged in, which were representations of actual battles. Five or six warriors appeared as Crow Indians, and the same or a less number were the Blood Indian warriors. A single horse represented that they had been on horseback, and this was decked in its war-paint. One of the men, the hero of the battle, acted as instructor of the ceremonies to the others. Four times they entered the lodge, and then the fight began. They fired their guns over the heads of the people; the Crow Indians fell one by one; and when they had been scalped, amid the laughter and applause of the audience, the scene was at an end. Berries cooked in fat were brought in by the women in pails and pots; and for a short time eating, smoking, and conversation were the duties of the hour. Occasionally some old lady would call out the name of a young man, and declare his noble qualities before the people; and another would urge the young men to emulate the heroic deeds of their fathers, and go to war.

Presents of bracelets, finger-rings, and ear-rings were made to some of the women. The chief warrior carried in his hand the sacred pipe, which he first held aloft with the stem toward the sun, that he might have the first-fruits of every thing; and still holding it,

stem toward the chiefs, each was allowed to take a smoke. The pipe was beautifully ornamented, and was used only at the sun-dance. Some of these pipes are of great value, the one seen costing fifteen of the best horses in the tribe, and these were used for hunting the buffalo. The women have one important ceremony to perform; namely, the preparation of the tongues. In former years, when buffalo were in abundance, as many as two thousand buffalo-tongues were used at a single sun-dance: now the Indians have to be contented with two hundred tongues of domestic cattle. These are slightly boiled and dried, cut in slices very carefully, taken in sacks to the sun-lodge, and guarded by two young men. This rite partakes of the nature of a sacrament. None but virtuous women are allowed to go up and take a piece of tongue. After the persons devoted to the sun have partaken of the meal, the rest of the tongues are distributed among the people as a religious ceremony.

At this time a young Indian went to an old medicine-woman and presented his sacrifice to the sun. During the year he had gone on a horse-stealing expedition, and, as is customary on such occasions, had prayed to the sun for protection and success, offering himself to his god if his prayers were answered. He had been successful, and he now presented himself as a sacrifice. The old woman took his hand, held it toward the sun, and prayed; then, laying a finger on a block of wood, she severed it with one blow of a knife. She held the portion of the finger cut off toward the sun, and dedicated that to him as the young man's sacrifice.

One of the principal features of the sun-dance is the self-torture of those who are admitted as warriors. Dr. McLean witnessed one of these ceremonies. Two young men, having their whole bodies painted, wearing the loin-cloth only, and with wreaths of leaves around their heads, ankles, and wrists, stepped into the centre of the lodge. A blanket and a pillow were laid on the ground, and one of the young men stretched himself upon them. As he lay, an old man came forward and stood over him, and then in an earnest speech told the people of the brave deeds and noble heart of the young man. In the enumeration of his virtues and noble deeds, after each separate statement the musicians beat applause. When the aged orator ceased, the young man arose, placed his hands upon the old man's shoulders, and drew them downward, as a sign of gratitude for the favorable things said about him. He lay down, and four men held him, while a fifth made the incisions in his breast and back. Two places were marked in each breast, denoting the position and width of each incision. This being done, the wooden skewers being in readiness, a double-edged knife was held in the hand, the point touching the flesh, a small piece of wood was placed on the under side to receive the point of the knife when it had gone through, and the flesh was drawn out the desired length for the knife to pierce. A quick pressure, and the incision was made, the piece of wood was removed, and the skewer inserted from the under side as the knife was being taken out. When the skewer was properly inserted, it was beaten down with the palm of the hand of the operator, that it might remain firmly in its place. This being done to each breast, with a single skewer for each, strong enough to tear away the flesh, and long enough to hold the lariats fastened to the top of the sacred pole, a double incision was made on the back of the left shoulder, to the skewer of which was fastened a drum. The work being pronounced good by the persons engaged in the operation, the young man arose, and one of the operators fastened the lariats, giving them two or three jerks to bring them into position.

The young man went up to the sacred pole, and, while his countenance was exceedingly pale, and his frame trembling with emotion, threw his arms around it, and prayed earnestly for strength to pass successfully through the trying ordeal. His prayer ended, he moved backward until the flesh was fully extended; and, placing a small bone whistle in his mouth, he blew continuously upon it a series of short, sharp sounds, while he threw himself backward, and danced until the flesh gave way and he fell. Previous to his tearing himself free from the lariats, he seized the drum with both hands, and with a sudden pull tore the flesh on his back, dashing the drum to the ground amid the applause of the people. As he lay on the ground, the operators examined his wounds, cut off the flesh that was hanging loosely, and the ceremony was at an end.

In former years the head of a buffalo was fastened by a rope to the back of a person undergoing the feat of self-immolation, but now a drum is used for that purpose.

From two to five persons undergo this torture every sun-dance. Its object is military and religious. It admits the young man into the noble band of warriors, whereby he gains the esteem of his fellows, and opens up the path to fortune and fame. But it is chiefly a religious rite. In time of sickness or danger, or in starting upon some dangerous expedition, the young man prays to the sun for help, and promises to give himself to the sun if his prayers are answered. Upon his return, when the annual sun-dance is held, he fulfils his vow, gives himself to his god, and thus performs a twofold duty. Of course, the applause of the people and the exhibition of courage are important factors in this rite, but its chief feature is a religious one. Instead of being a time of feasting and pleasure, the sun-dance is a military and religious festival, in connection with which there are occasions for joy, and the feast enhances the pleasure.

During the feast the entire assemblage will burst forth in songs of thanksgiving, and again a famous warrior will sing aloud the praises of a young man or some brave kinsman who merits the applause of the tribe. This is a kind of chant, in which the name and noble deeds are spoken of.

A SURVIVAL OF CORPORAL PENANCE.—The state of mind from which the infliction of self-torture arises is not confined to primitive people, but has manifested itself in all great religions of the world. In the middle ages the Order of the Flagellants was devoted exclusively to this purpose. A survival of this once powerful organization offers an interesting comparison to the practices of the Blackfeet, just described. This was observed to exist by Mr. O. H. Howarth in the village of Fenaës d'Ajuda on the Azores, and has been described by him in a recent number of the *Journal of the Anthropological Institute*. The Order of the Ferceiros in that place now consists of a body of from fifteen to eighteen lay inhabitants of the parish, who are admitted to it by election every seven years; the order being held in such reverence, and the efficacy of the penance so profoundly believed in, that vacancies are much sought after. The ceremony takes place annually in connection with the procession of N. S. dos Passos on the third Sunday in Lent. The costume of the Flagellants is a white linen tunic, with a large oval opening in the back for the purpose of flagellation; and the head of the performer is entirely concealed with a wrapper of white linen, so that his identity may be unknown to the general spectators. Mass is conducted by the priest, and the flagellation commences when the church is darkened in the course of the Lenten ritual, the order kneeling in two rows at each side of the chancel. It is continued throughout the procession which follows. The principal streets of the village are traversed, and the self-punishment is inflicted with special violence during pauses at the street-corners, when the members of the band seem to vie with one another in the severity of their discipline. The procession returns to the church; the flagellants resuming their former position, and continuing to scourge themselves with increasing vigor until the conclusion of the ceremony. The torture is carried to such extremities that the side walls, railings, and confessionals in the chancel are smeared and spotted with blood to a height of four or five feet. The type of the scourge and flagellum are such that the author concludes the institution to be kept up by unbroken tradition from the middle ages, the implements being of the same description as those used six centuries ago by the Flagellants.

ELECTRICAL NEWS.

SMALL ENGINES FOR ELECTRIC LIGHTING.—The Society of Arts in England having offered a gold medal for the best small engine to be used for electric lighting, some tests have just been published giving the results of the trial. There were four competitors, — three gas-engines, and a high-speed high-pressure steam-engine. As the machines are especially useful for isolated lighting plants, the results give some valuable data as to the cost of lighting by electricity as compared with gas. One of the three gas-engines,

the Otto, is well known in this country. A mixture of gas and air is admitted into the cylinder and ignited, the explosion giving the motive power. The arrangement is such that the engine receives one impulse in every two revolutions; so, in order to get a steady motion, an extremely heavy fly-wheel, or a countershaft carrying a fly-wheel, is necessary. Another of the gas-engines, the Atkinson, is of rather remarkable design. There are four strokes of the piston to one revolution of the fly-wheel, and these strokes are of varying length. The stroke which takes the charge into the cylinder is 6.3 inches; the next stroke compresses the charge, and is 5 inches in length, the charge being thus compressed into a space of 1.3 inches. The compression being effected, ignition takes place, giving the working stroke, which is 11.13 inches in length. This is followed by the exhaust stroke, which sweeps the products of combustion out, and is 12.4 inches in length. The cylinder is 9.5 inches in diameter. The third of the gas-engines, the Griffin, differs from the other two in several particulars. An impulse is given to the crank-shaft for every revolution and a half. The tests were made by Professor A. C. W. Kennedy, Dr. John Hopkinson, and Mr. Beauchamp Tower. Taking first the Atkinson engine, they found that the gas consumed per indicated horse-power was 18.8 cubic feet, and per brake horse-power 22.1 cubic feet per hour. The gas used for ignition was 4.5 cubic feet per hour, making a total per brake horse-power of 22.6 cubic feet per hour. The engine ran smoothly and with regularity. The mechanical efficiency of the engine was 85 per cent, and 25.5 per cent of the whole of the heat generated was converted into work. The Otto engine used 27.4 cubic feet of gas per hour for an available horse-power. The Griffin engine used 28 feet per hour for an available horse-power. These figures show, that, as far as the cost of gas is concerned, it is more economical to use it to drive an engine, and use the power developed for electric lighting, than to burn it directly. For instance: if we take 25 cubic feet of gas per hour as the average amount consumed per horse-power by a gas-engine, then we have, by burning direct, 5 16-candle-power gaslights; with gas-engine and dynamo, 12 16-candle-power electric lights. There are at present, however, so many additional expenses incident to an isolated electric plant,—interest, depreciation, breakage, attendance, etc.,—that it is cheaper to use the gas directly. At the same time, the figures given suggest possibilities. The fourth engine tested was a Davy-Paxman steam-engine of about twenty horse-power. This gave some remarkable results. It is a compound engine, the cylinders being 5.24 and 8.93 inches in diameter, and the stroke 14 inches, the pressure used being 100 pounds. The result of one of the trials was an available horse-power for 2.08 pounds of coal per hour,—a remarkable result, considering the size of the engine. These results show, that, as far as cost of fuel alone is considered, a horse-power hour from a gas-engine, with gas at \$1.50 per thousand feet, would cost 3.75 cents; and from a Davy-Paxman engine, with coal at \$4 per ton, .8 of a cent.

ACCUMULATORS.—Judge Coxe has just rendered a decision in the United States Circuit Court for the southern district of New York, in which the Faure patent for improvements in secondary batteries or accumulators is held to cover any secondary battery in which an electrode is used having the so-called active material applied in the form of a paint, paste, or cement. The suit is entitled "The Electrical Accumulator Company vs. Julien Electric Company." The field for accumulators is very large, as shown by the fact that there are to-day no less than eight or ten companies engaged in that business. Among them are the Electrical Accumulator Company, owning the Faure patents, and the Julien, Gibson, Woodward, Pumpelly, and Macraon Companies, all of whose batteries, the Accumulator Company claims, are tributary to the Faure invention. In anticipation of a favorable decision, the Electrical Accumulator Company has already built a street-car to be propelled by means of batteries, and now has it on exhibition on Elkins & Widener's Philadelphia Traction Road in West Philadelphia. Its initial trip last Friday was a success, the car moving up a long five-per-cent grade at the rate of seven miles an hour. Brill & Co., West Philadelphia, are making six other cars to be completed in April and May; and the Electrical Accumulator Company is now prepared to occupy extensively the electric street-car field.

NOTES AND NEWS.

DR. R. W. SHUFELDT has moved from Fort Wingate, N.Mex., to Washington, D.C., where he will continue in his scientific pursuits at the Smithsonian Institution.

—The wind-pressure on the Forth bridge, or rather the effective area of a bridge exposed to a wind-pressure striking the work at different angles, was practically demonstrated by Mr. B. Baker, as described in a late lecture before the Society of Arts, as follows: a model of the bridge was made, and towed in water at different angles to the stream; the area of a flat board normal to the current was then determined, which exerted the same drag as the model; this area was then taken as the effective area of the bridge for the particular angle at which it was towed.

—M. Alfred Binet of Paris, France, will contribute to *The Open Court* (Chicago) of March 21 a paper on "Sensation and the Outer World." The article is part of an unpublished essay upon "External Perception," crowned by the Académie des Sciences Morales et Politiques. In the same number Professor Edward D. Cope of Philadelphia will present some considerations upon ethical evolution, including a review of the extent and significance of the utilitarian doctrine of morals. *The Open Court* of March 28 will contain an article by the German Sanscrit scholar, Professor H. Oldenberg, on the "Discovery of the Veda." The disclosures that this epoch-making event have led to, form the most interesting chapter in all philological science.

—The composition and evaporative power of Kansas coals have been investigated by Professor E. H. S. Bailey and Professor L. I. Blake, of the State University. The coal-measures that underlie the eastern part of the State of Kansas are being developed at the present time to a greater extent than ever before. With the increased population of the State, the introduction of important manufacturing, and the extension of so many lines of railway, there is naturally a greater demand for fuel, and a greater interest in its economic supply. In the last "Report of the State Mine Inspector" (1887), there are mentioned about a hundred shafts, in the different regions, where mining is actively carried on; besides this, there are innumerable places where coal is mined or stripped in a small way to supply the local trade. The coal-beds seem to be divided into several groups, the lowest being in the extreme south-eastern part of the State. The coals depreciate in their steam-producing powers from the south-eastern part of the State toward the north and west. Professor Bailey finds they depreciate in the amounts of fixed carbon in a similar order.

—The Johns Hopkins Hospital will be opened to the inspection of the public, before the reception of patients, during the week beginning May 6, 1889. On Tuesday, May 7, at 11 o'clock in the morning, there will be appropriate addresses in the main administration building. Invitations to be present will be sent to the authorities of the city and State, to those who have rendered special services in promoting the plans of the hospital, to professors of medicine and surgery, to the chief managers of other hospitals, and to the representatives of the press. On Wednesday, May 8, between the hours of 12 and 6 o'clock, the buildings will be open to the medical profession of Baltimore, Washington, and the State of Maryland, to medical students, to the managers of the benevolent institutions of Baltimore, to the ministers of all religious denominations, and to other persons whose pursuits have led them to take a special interest in hospital-work. Cards of admission will be distributed in advance. On Thursday, May 9, and Friday, May 10, between the hours of 12 and 6 o'clock, the public generally will be invited to visit the hospital. Cards of admission may be obtained, on the days named, at the entrance-gate of the hospital, Broadway. On Saturday, May 11, the faculties of the various institutions in Baltimore, the teachers of public and private schools of every kind, the students of the Johns Hopkins University, the Baltimore City College, the State Normal School, the Woman's College of Baltimore, and the Eastern and Western Female High Schools, will be admitted between the hours of 10 and 6 o'clock upon the presentation of tickets, which will be distributed in advance. The dispensary will be opened for the treatment of out-door patients, Monday, May 13, at 10 o'clock. The hospital will be opened soon afterwards for the treatment of patients.

DR. WILLIS G. TUCKER, analyst of drugs, has made his eighth annual report to the State Board of Health of New York. He has collected and analyzed 326 samples of drugs, and pharmaceutical chemicals and preparations. These include acetic acid, calomel, chloroform, ether, glycerine, iodoform, tincture of chloride of iron, lime-water, saffron (*Crocus*), santonine, and sulphur. Forty-three per cent were found of good quality; 13.5 of fair quality; and 24.2 of inferior quality; and 19.3 not as called for, that is to say, substituted articles, as, when saffron (*Crocus*) was asked for, common safflower was sold. Fifty-three samples of stronger ether were examined. Of these, 20 were of good quality, 5 fair, 26 inferior. One sample was spirit of nitrous ether, and another the so-called "concentrated nitrous ether." As Dr. Tucker says, such errors as these are the grossest of blunders, and the consequence of such ignorant or careless sales might be most serious to the purchaser. As stronger ether is used as an anæsthetic, it ought to be of good quality. If the samples examined by Dr. Tucker represent the true condition of affairs throughout the world, it is not surprising that evil results sometimes follow the use of ether as an anæsthetic, as his results show that more than 50 per cent of the ether he tested was of inferior quality. Dr. Tucker expresses the opinion that the work done during the past two years has had a decided effect in improving the quality of the drugs sold throughout the State.

THE ADIRONDACK FORESTS.

As the majority of persons are interested in the preservation of our forests in the East, the arguments of *Garden and Forest*, in its issue of March 6, in favor of State control, will probably meet with some response. It is hardly likely that the direful picture which the writer of the article would bring before our mental vision will be realized; since the State of New York varies little in its commercial environment from New England, and in New England the tree-covered area has been on the increase for fifty years. So, while the constant change from freshet to drought may never be the fate of northern New York, yet the primeval forests may be gone as a pleasure-ground. The editor of *Garden and Forest* argues as follows:—

The complete destruction of the Adirondack forests is inevitable if existing conditions and methods of treatment are to continue. Unimportant improvements in the details of their management may be made from time to time; such improvements have been made within the last few years, and others are now proposed; but the processes of destruction are much more rapid and extensive than the effect of these comparatively insignificant means of amelioration, and there is at present no reason to expect that any effective provision will be made for the permanent protection of any part of this important region. Nothing can be done, indeed, without a thorough change in the system of control and administration of the forests on the State lands. The methods now pursued interpose no serious check to the influences which will extirpate the woods in a comparatively short time. If the devastation of the region, already far advanced, is completed, centuries of time will be required for any process of restoration.

The destruction of the North Woods will produce a change in the flow of the principal rivers of the State, and in the water-supply of the Erie Canal, which will cause widespread disaster to the interests of the people. There will be uncontrollable freshets at the times of heaviest rainfall, and when the snow melts in the spring; the channels of the rivers will be choked by *débris* brought down from the hills; and in summer, when a full volume of water is most needed, the flow will be insignificant. If this ruin is consummated, it will be a most serious blow to the prosperity of the State and of all classes of its people.

Not less important is the value of the region, in its relation to the health and life of the people of the country, as a place of resort for the inhabitants of the towns, and for all who need the restorative and vitalizing atmosphere and influences of a region of sylvan beauty and peace. As our population becomes more dense, the need and value of wild, rough tracts, incapable of cultivation, will be greatly increased. Beyond the arrangement required for the subsistence and comfort of the multitudes of visitors, no settlement or inhabitation should be permitted in any part of the wilderness. If the forests are destroyed, the entire charm and attractiveness of the region will be eliminated, and a scene of hideous desolation will be substituted which no one will ever wish to look upon.

The only plan by which such injury can be averted, and means provided for the permanent conservation of these invaluable forests, is the acquisition by the State of the entire Adirondack region. While portions of it remain in the hands of private owners, injuries to State lands adjacent to their holdings cannot be prevented. But it would be senseless and wicked to expend the money which would be required for this purpose while the present system of control continues. It has proved entirely inadequate for the protection of the forests on the lands which already belong to the State, and it would be the extreme of folly to acquire property at great cost when there is danger that it might soon be dissipated and destroyed.

Unless a system of permanent control, under competent direction, can be put in operation, the people of New York may as well relinquish all thought of saving the Adirondack forests, and all interest in the subject. There can be no adequate or successful administration of a great forest-preserve while its management is subject to the possibility of frequent change, because it is treated as a portion of the political patronage of the State government. Unless the care of the forests on the State lands can be placed in the hands of men of such known and obvious character and quali-

fication for this work as will inspire general confidence, no system of administration can be successful, and competent men will not accept a place of such responsibility and importance while their work is always liable to interruption by the agencies of partisan politics. The inadequacy and failure of the present system of control and administration are inherent in the system itself, and are inseparable from its relation to partisan change and caprice. The evil is not to be remedied by merely changing the persons who administer a system which is essentially vicious.

If the people of the State of New York have enough regard for their own interests to lead them to insist upon the adoption of a system embodying the essential features of competent direction and security from partisan interference, it will be safe and wise to acquire the whole Adirondack region by purchase. If they have not this perception of the importance of the object in view, and of the means which are necessary for its accomplishment, the forests will be left to their fate. The methods now employed are wholly useless and ineffective.

THE UTILITY OF AGRICULTURAL EXPERIMENT STATIONS.

The Hon. W. W. Wright, in a recent address on the past and present work and future prospects of the Geneva station, New York, took occasion to uphold the usefulness of such stations. The establishment of an experiment station by the State near Geneva within the last seven years challenged a great deal of curiosity among farmers and others, and is of late creating more and more of interest. To most people it was entirely new, nothing of the kind being nearer than adjoining States; and it may be said to be a modern invention, but cannot be called a "Yankee contrivance," for England, France, Germany, and other European countries, led off in the creation of these establishments within the present century, and had expended many millions of dollars in their organization and maintenance before any of the American States had established one. New York was among the last to avail itself of these institutions, though its wealth, extent of territory, and diversified agricultural interests, would naturally have made it the first. In one sense, such a "station" is no "experiment." In its organization, management, and the results to be expected, we have only to look to other civilized countries, which have had an experience, in some cases, of nearly forty years. When the Legislature of New York passed the law for creating this station, the significant fact was before us that neither in this country, nor in any other, had these stations been established, except they had fully answered the expectations of their projectors, and had been cherished and sustained, because their benefits were so manifest that there was no hesitation about continuing appropriations for their maintenance. Agricultural colleges, and classes in universities in which scientific farming was taught, were established or endowed in New York, but they cannot be said to have been successful. The most extensive of them was totally abandoned after a few years; whereas no experiment station has ever been discontinued, or diminished in the scope of its work, or embarrassed in the want of funds, in this country or Europe. On the contrary, in foreign countries they have been multiplied to an enormous extent, and have steadily increased on this side, though not so rapidly. There must be some reason for the success of these stations, and the total or partial failure of the colleges. The truth is, they are both schools, in which there is little difference in the abilities and qualifications of the teachers, but there is a vast disparity in the number and character of the students. In colleges we teach a few hundred boys, only a small percentage of whom will become practical farmers; while the stations are endeavoring to teach the same science to a whole community of men of all ages and conditions, engaged in the business of agriculture, not alone through lectures in which the relations of science and practical farming are explained, but through the agricultural press, and pretty much all newspapers now published and circulated in this country, daily, weekly, and monthly; and these are supplemented by bulletins giving in detail appropriate facts and statistics of the greatest interest to those who desire to become better informed in a business which occupies their constant thoughts, and in most cases the labor of their hands.

Through these channels the stations reach the whole agricultural community. Nobody is too illiterate to participate in this knowledge, if he can read, or understand what others read to him. Nobody is too old to learn in this "school;" and he soon becomes almost unconsciously a teacher himself, for he imparts the knowledge he has thus acquired to others, in farmers' clubs and neighborhood gatherings, in the village tavern or post-office, at the country firesides, in the fields and on the highways, in an unpretentious but none the less effective and valuable way. He tests the theories of the professors, lecturers, and newspaper-writers by his invaluable practical knowledge and common sense, and often detects the errors into which theorists are always liable to fall, and thus renders valuable service to the true interests of agriculture. It may happen in this way that men who have never learned to read or write, but are capable of managing a farm well, may become valuable teachers in a limited sphere.

The first agricultural experiment station was established in Germany in 1851, and since that time the number of stations has steadily increased, until at present the number in the German Empire alone is given as 184. Careful statistics, including nearly every country of Europe, show that if New York should expend an equal amount, proportioned to the area of our territory, we should expend one million dollars annually. If, on the other hand, it were proportioned to our population, it would require an annual expenditure of three hundred thousand dollars before we should be on a level with the countries of Europe. The first station, as has been stated, was established in 1851 at Moeckern in Saxony; five years after, there were 6 stations in existence; five years later, 15; in 1866, 30; and in 1871, 56; since which time they have been even more rapidly increased.

Those who may perhaps regard the work done at Geneva as rather of scientific than practical value will be gratified to learn what work was entered upon and continued at this first station at Moeckern during the first six years of its existence. This is given in a summary recently prepared, comprised under twenty-six different heads. We select but a few of them: 1. Feeding-trials with sheep to ascertain the best maintenance rations; 2. Feeding-trials with cows, showing effect of colesseed-cake on yield of milk; 3. Feeding-trials on fattening sheep; 4. Observations on the yield of manure of cows and sheep, and the changes it suffers by keeping; 5. Comparison of feeding-value of grass, hay, and aftermath; 6. Observations on milk-production in passing from winter to summer feeding; 7. Effect of lupines on milk-production; 8. Composition and value as food of various kinds of distillery and brewery waste; 9. Feeding-trials with cows, oxen, and calves, the proper proportion of nitrogenous and non-nitrogenous food-elements for the three classes of animals, etc.

THE ENCOURAGEMENT OF HIGHER EDUCATION.¹

THE choice of the 22d of February for the founder's day of the Johns Hopkins University will always be recognized as singularly appropriate. Historic associations, at once local and national, determined the choice.

It is a fact not generally known that the Father of his Country, before he became President of the United States, was the president of a Virginia college. When Washington was chosen to the office of chancellor of William and Mary College, succeeding the Bishop of London in that educational honor, he assured the board of trustees of his firm confidence "in their strenuous efforts for placing the system of education on such a basis as will render it the most beneficial to the State and the republic of letters, as well as to the more extensive interests of humanity and religion." Washington was always the friend of William and Mary College, his *alma mater*. Without forgetting local institutions in Virginia, he advanced during his eight years' presidency of the United States to what may be called the national idea in university education. From that idea Baltimore to-day can derive encouragement and inspiration.

Washington's grand thought of a national university, based upon individual endowment, may be found in many of his writings, but

¹ Abstract of an address by Professor Herbert B. Adams, Johns Hopkins University, Feb. 22, 1889.

the clearest and strongest statement occurs in his last will and testament. There he employed the following significant language: "It has been my ardent wish to see a plan devised, on a liberal scale, which would have a tendency to spread systematic ideas through all parts of this rising empire, thereby to do away local attachments and State prejudices, as far as the nature of things would, or indeed ought to admit, from our national councils. Looking anxiously forward to the accomplishment of so desirable an object as this is, in my estimation, my mind has not been able to contemplate any plan more likely to effect the measure than the establishment of a university in a central part of the United States, to which the youths of fortune and talents from all parts thereof may be sent for the completion of their education, in all branches of polite literature, in arts and sciences, in acquiring knowledge in the principles of politics and good government, and, as a matter of infinite importance in my judgment, by associating with each other, and forming friendships in juvenile years, be enabled to free themselves in a proper degree from those local prejudices and habitual jealousies which have just been mentioned, and which, when carried to excess, are never-failing sources of disquietude to the public mind, and pregnant of mischievous consequences to this country. Under these impressions, so fully dilated, I give and bequeath, in perpetuity, the fifty shares which I hold in the Potomac Company, . . . towards the endowment of a university, to be established within the limits of the District of Columbia, under the auspices of the general government, if that government should incline to extend a favoring hand towards it."

Here was the individual foundation of a national university. Here was the first suggestion of that noble line of public policy subsequently adopted in 1846 by our general government in relation to the Smithsonian Institution. The existence and ever-increasing prosperity of the Smithsonian Institution are standing proofs that private foundations may receive the fostering care of government without injurious results. Independent administration of scientific institutions may co-exist with State aid. It is a remarkable testimony to the wisdom of George Washington's original idea, that Andrew D. White, who, when president of Cornell University, happily combined private endowments and government land-grants, lately suggested in *The Forum* (February, 1889) the thought of a national university upon individual foundations. This thought is a century old, but it remains to this day the grandest thought in American educational history.

George Washington, like James Smithson, placed a private bequest, so that the general government might extend to it "a favoring hand;" but in those early days Congress had no conception of the duties of government towards education and science, and unfortunately the Potomac stock never paid but one dividend. George Washington's educational schemes were by no means visionary. His stock in the James River Company, which, like the Potomac Company, he had helped to organize, actually became productive, and was by him presented to Liberty Hall Academy, now Washington and Lee University. Washington raised Liberty Hall Academy to what he called "a seminary of learning upon an enlarged plan, but not coming up to the full idea of university." He meant to make it one of the three Virginia supporters of the university at Washington. Liberty Hall, or Washington College, his own William and Mary, and Hampden-Sidney, were all to be state pillars of a national temple of learning.

Was it not in some measure an historic, although an unconscious, fulfilment of that old dream of Washington, when, a hundred years later, Johns Hopkins determined to establish upon the Maryland side of the Potomac a university? Doubtless Johns Hopkins, like George Washington, had no very definite conception concerning the world-wide relations of a great modern university; but he saw as clearly as did the Father of his Country that the beneficent influence of higher education, if properly endowed, must reach far beyond the limits of a single State.

The Baltimore public has been accustomed to see or hear some new thing every year with regard to the number of students from this city, from Maryland, Japan, and each individual State of the American Union. The following facts represent a novel grouping of students according to the great sections of country from which they come. There have been some misapprehensions in our com-

munity concerning the region benefited by this university. Our new arrangement of statistics shows that during the present year there have been studying at this institution 98 graduates from the South, 47 from the West, 26 from the Middle States, 18 from New England. It is plain that this university is drawing college-men from the same sources as those from which Johns Hopkins drew his wealth; namely, from the South and West. In the undergraduate department there are now 139 students from the South, 18 from the West, 14 from the Middle States, and 4 from New England. Plainly, most of "our boys" come from the same sections of country as our graduates. The sum total of men from the South is 237; from the West, 65; from the Middle States, 40; from New England, 22. In short, the South has more than three and one-half times as many representatives as the West, six times as many as the Middle States, and more than ten times the number from New England. The total number from all the other States combined is nearly doubled by the South. About one-half of our entire student public comes from the State of Maryland. Considerably more than one-half comes from the three Southern States which Johns Hopkins wished especially to benefit. From this brief review of statistical facts, four points are clear: first, the intent of our founder has been realized; second, the South and the West are chief sources of our student-supply; third, in these directions are the lines of least resistance and greatest influence for the Johns Hopkins University; fourth, one-half of our student public comes from other States than Maryland,—a fact indicating that the local idea is happily balanced by the national idea.

There are pleasing evidences of internationality in the life and influence of the Johns Hopkins University. Some of our professors came hither from England and Germany. Almost all the members of our faculty have studied at one time or another in European institutions. The annual register for 1888 shows twelve students from Canada, seven from Japan, and one representative from each of the following countries: China, England, Germany, Mexico, Italy, and Russia.

Of the graduates, we see Westerners called eastward to college positions, Northerners called southwards, and Southerners called northwards. The president and trustees of the Johns Hopkins University have established here a national university upon a local and individual foundation.

How can the foundations of a national university, resting upon individual endowment, be further strengthened? Simply by extension and more endowments of the same sort. A great university grows, as a great city grows, by the individual association of property investments along avenues already opened. There are men who dream of founding towns and universities apart from existing centres of population and capital; but he is a wise founder who, like George Peabody, Johns Hopkins, or Enoch Pratt, recognizes the vantage-ground of a noble city, and plants there institutions which will work together through coming ages. The principle holds with reference to individual endowments for the higher education. They always accomplish the most good when they are connected with some central foundation which gives them at once stability, unity, and individuality, as in the associated institutions of a large city.

Extension by private philanthropy is the manifest destiny of the Johns Hopkins University. There will perhaps be the individual endowment of a college; perhaps of a university library, bearing the name of the giver, like the Andrew D. White Library at Cornell University; of a laboratory, a museum, or an observatory, like those at Harvard or at the University of Virginia. Some day we ought to have an art-gallery like that at Yale. What is most needed, however, is a central academic building and library to shelter fitly the "fair humanities,"—the studies of ancient and modern literature; philosophy and ethics; history, politics, and social science. Baltimore, in the course of time, will have as many foundations, bearing individual names, as there are now in the older institutions of the country. Glance through the catalogues of Harvard, Yale, Princeton, or the University of Virginia, and see the great host of private bequests, some large, some small, but all of them carefully guarded and applied to specific objects, such as the increase of the library or the support of scholarships and fellowships. There may be as much individuality in a great university

establishment as there is in a street or a city bearing a great man's name, like Washington Place or Baltimore.

This is an era of educational endowment upon a generous scale. The most recent published report of Col. Dawson, the commissioner of education, shows that the sum total of noteworthy educational gifts during the year 1886-87 was nearly five million dollars. More than two-thirds of the entire amount was distributed among nine institutions, four of them collegiate, one academic, three professional, and one technical. The institution most highly favored was Harvard University, which received from individual sources nearly a million dollars. From one man came a legacy of \$630,000. Our nearer neighbor, Haverford College, supported by the Society of Friends, received \$700,000 in one bequest. Of the 209 gifts recorded by the commissioner of education, 25 represent \$50,000 or more, 72 were sums between \$5,000 and \$49,000, and 112 were sums less than \$5,000. The most striking fact in all this record of philanthropy is that such a large proportion of the entire amount, fully two-thirds, was given to higher education. The year 1888 is richer than 1887 in individual bounty to institutions of learning. Nearly ten millions were given by three persons for the encouragement of manual training, etc., but there are rumors of even larger benefactions for university endowment. The collective returns for 1888 are not yet published, but it is certain that the past year will surpass any hitherto recorded in the annals of American education.

Whatever forms modern philanthropy may take, one thing is certain, universities are not likely to be forgotten. While the Johns Hopkins University undoubtedly has most to expect from private philanthropy, like that which has already built up the city, it is not beyond the bounds of possibility to hope that the State of Maryland may some day extend to our institution what George Washington modestly called a "favoring hand." At present this State, by the exercise of its taxing power, takes from the Johns Hopkins the sum of nearly \$1,100,000, and from the Johns Hopkins Hospital the sum of \$33,000, a year. From our original patrimony Baltimore County took a collateral inheritance tax of \$36,000.

The exemption of college property, even the property of professors, from taxation was well-nigh the universal custom in the English colonies of North America. To this day, Maryland exempts from taxation all buildings, furniture, equipments, and libraries of incorporated educational or literary institutions, with the land appertaining to them; in other words, all unproductive property actually in use for educational purposes. This principle of exempting the property of institutions of learning is so thoroughly embedded in the constitutional, statutory, and customary law of almost every State in the American Union, that such exemption may be recognized, like the principles of Roman law, as sovereign common sense. But some American States go much further, and exempt the productive property of colleges and universities, their savings and investments, the income of which is applied to educational objects. The personal property and real estate belonging to educational institutions are exempt from taxation in each of the following States: Maine, Vermont, Rhode Island, Virginia, Kentucky, Kansas, and Nebraska, and probably in others whose statutory laws permit exemption but whose customs and policy vary.

Exemption from taxation is a manifest duty which the State of Maryland owes to an institution which is now using all the income from its productive capital, as well as its buildings, books, and apparatus, for the higher education of Maryland youth. Indeed, one might go further, and say that the Johns Hopkins is doing for Maryland what most States endeavor to secure by large annual appropriations. This institution is to-day discharging the functions of a State university, and is paying for the privilege of providing what is usually regarded as the duty of the State to provide.

The encouragement of higher education by government aid, in one form or another, has been a recognized principle of public policy in every enlightened State, whether ancient or modern. Older than the recognition of popular education as a public duty was the endowment of colleges and universities at public expense for the education of men who were to serve Church or State. It is a mistake to think that the foundation of institutions by princes or prelates was a purely private matter. The money or the land

always came from the people in one form or another, and the benefit of endowment returned to the people sooner or later. Popular education is the historic outgrowth of the higher education in every civilized country, and those countries which have done most for universities have the best schools for the people. It is an error to suppose that endowment of the higher learning is confined to Roman and German emperors, French and English kings. Crowned and uncrowned republics have pursued the same public policy. Indeed, the liberality of government towards art and science always increases with the progress of liberal ideas, even in monarchical countries like Germany, where, since the introduction of parliamentary government, appropriations for university education have greatly increased. The total cost of maintaining the Prussian universities, as shown by the reports of our commissioner of education, is about two million dollars a year. Only about nine per cent of this enormous outlay is met by tuition-fees. The State contributes all the rest in endowments and appropriations. Prussia now gives to her universities more than twice as much as she did before the Franco-Prussian war, as shown by the report of our commissioner at the Paris Exposition in 1867. In that year France gave her faculties of higher instruction only \$765,764. After the overthrow of the second empire, popular appropriations for higher education greatly increased. The budget for 1888 shows that France now appropriates for college and university faculties \$2,330,000 a year, more than three times the amount granted under Louis Napoleon. The little republic of Switzerland, with a population of only three millions, supports four state universities, having altogether more than three hundred instructors. Its cantons, corresponding upon a small scale to our States, expend over \$300,000 a year upon the higher education. The Federal Government of Switzerland appropriated, in 1887, \$115,000 to the polytechnicum, and \$36,000 in subsidies to cantonal schools, industrial and agricultural, besides bestowing regularly \$10,000 a year for the encouragement of Swiss art. The aggregate revenues of the colleges of Oxford, based upon innumerable historic endowments, public and private, now amount to fully two million dollars a year. The income of the Cambridge College endowments amounts to quite as much. But all this, it may be said, represents the policy of foreign lands. Let us look at home, and see what is done in our own American commonwealths.

Maryland began her educational history by paying a tobacco-tax for the support of William and Mary College. This colonial generosity to another State has a historic parallel in the appropriation of a township of land by Vermont for the encouragement of Dartmouth College in the State of New Hampshire, and in the corn that was sent from New Haven to the support of young Harvard. In colonial days Maryland had her county schools, some of them classical, like King William's School at Annapolis. All were founded by authority of the Colonial Government, and supported by aid from the public treasury. The principle of State aid to higher education runs throughout the entire history of both State and Colony.

The present generation has not been so generous to the cause of higher education as were the fathers of the State; but nevertheless Maryland, in her entire history, has appropriated something over \$650,000 for what may be strictly called college education, not counting \$60,000 given to the State Agricultural College, nor \$40,000 proceeding from State lotteries. While this collective bounty is small, it is money given by voluntary taxation, and not taken from institutions of learning. Most of the amount was raised in times when the State was poor or heavily in debt, and when public money came with difficulty. Moreover, this financial generosity of Maryland establishes the principle for which we are contending; namely, that this State, like all other enlightened States in the world, has recognized the duty of support to higher and unsectarian institutions of learning. She has at different times appropriated \$650,000 to colleges and the University of Maryland from her public treasury.

Let us now inquire what other States in the American Union have done for higher education, always recognizing of course great inequality in State population and in the taxable basis.

Virginia, whose earliest educational foundations Maryland helped to lay by her tobacco-tax, has expended upon colleges and univer-

sity over two million dollars during her history as a State, not counting the colonial bounty to William and Mary. Since the war, Virginia has given her university \$40,000 a year. Before the war, she gave \$15,000 a year. The original university establishment cost the State about \$400,000. The State of South Carolina was Jefferson's model for generous appropriations to the cause of sound learning. She has given two million and eight hundred thousand dollars to that object. Georgia has given \$938,000 for the same purpose. Louisiana has given \$794,000 from her State treasury for the higher education in recent years, and, according to the testimony of her own authorities, has distributed over two millions among schools, academies, and colleges. Texas has spent upon college education \$382,000, and has given for higher education two and one-quarter million acres of land. The educational foundations, both academic and popular, in the Lone Star State, are among the richest in America.

Turning now to the Great West, we find that Michigan has given over two million dollars to higher education. She supports a university which is as conspicuous in the North-west as the University of Virginia is in the South, upon one-twentieth of a mill tax on every dollar of taxable property in the State. That means half a cent on every hundred dollars. This university tax-rate yielded last year \$47,272. Wisconsin pays one-eighth of a mill tax for her university, and that yields \$74,000 per annum. Wisconsin has given for higher education \$1,200,000. Nebraska is even more generous to her State university: she grants three-eighths of a mill tax, yielding about \$60,000 a year. The State of California grants one-tenth of a mill tax, which yielded last year over \$76,000. Besides this, the University of California has a permanent State endowment of \$811,000, yielding an annual income of \$52,000, making a total of \$128,000 which the State gives annually to its highest institution of learning. Altogether California has expended upon higher education two and one-half million dollars.

It is needless to give further illustrations of State aid to American universities. These statistics have been carefully collected from original documents by one of our historical students, who are making important contributions to American educational history, to be published by the United States Bureau of Education. The principle of State aid to at least one leading university in each commonwealth is established in every one of the Southern and Western States. In New England, Harvard and Yale and other higher institutions of learning appear now to flourish upon individual endowments and private philanthropy; but almost every one of these collegiate institutions, at one time or another, has received State aid. Harvard was really a State institution. She inherited only £800 and 320 books from John Harvard. The towns were taxed in her interest, and every family paid its peck of corn to make, as it were, hockeak for President Dunster and his faculty. Harvard College has had more than half a million dollars from the treasury of Massachusetts. Yale has had about \$200,000 from the State of Connecticut. While undoubtedly the most generous gifts have come to New England colleges from private sources, yet every one of them, in time of emergency, has come boldly before representatives of the people, and stated the want. They have always obtained State aid when it was needed. Last year the Massachusetts Institute of Technology became somewhat embarrassed financially, and asked the Legislature for \$100,000. The institution got \$200,000, twice what it asked for, upon conditions that were easy to meet.

Can the State of Maryland and the friends of the Johns Hopkins ignore the abundant testimony in favor of the encouragement of university education, not only by exemption from burdensome taxation, but by positive appropriations? If occasion arises, it will be proper and legitimate for the friends of this institution to go before the people of Maryland and say what is needed. Private philanthropy will do all it can, but public interest demands that the State should do its part by throwing off needless taxes, and settling for what it has already taken away.

Do you say that all this would lead to meddling interference by the politicians? That is what everybody said when a university was founded by the Prussian Government in Berlin. That is the stock argument against all State universities. But there stand today Berlin and all the German universities firm and untroubled

upon state foundations. The whole South and the entire West are full of educational establishments by the State. Some of them, like the Universities of Virginia, Michigan, and Wisconsin, are beacon lights of intelligent and non-partisan administration. Have Washington politicians done any harm to the Smithsonian Institution? On the contrary, they have indirectly increased its economic power by appropriations amounting to nearly two million dollars. They allow the secretary of the Smithsonian to direct the expenditure of \$220,000 a year. Congress allows the Smithsonian to be managed by a board of regents composed of distinguished college presidents and public men of spotless integrity. Amid all the changes in the civil service, no man has ever been displaced for political reasons from either the Smithsonian Institution or the National Museum. These facts are stated upon good authority.

What are the serious thoughts that have been emphasized in this address?

1. The Johns Hopkins is now a truly national university upon local and individual foundations.
2. This noble institution which benefits Baltimore, Maryland, and the whole country, especially the South and West, can be strengthened most efficiently by further local and individual endowments.
3. The examples of history at home as well as abroad show that States encourage universities by wise exemption from burdensome taxation and by generous appropriations, if original endowments and private philanthropy prove inadequate.
4. The development of public opinion, based upon a knowledge of present facts and upon existing relations of this university to Baltimore and Maryland, is the best way to encourage higher education in this city, in this State, and in this country.

BOOK-REVIEWS.

The Government of the People of the United States. By FRANCIS NEWTON THORPE. Philadelphia, Eldredge & Brother. 12^o. 90 cents.

WORKS on the American system of government multiply apace; and, if their quality was always good, our young people would have superabundant means of information about their public duties. Candor compels us to say, however, that the treatise now before us is defective in some very important respects. Its chief fault is that it attempts too much. It undertakes to describe not only the Federal Government, but also those of the States, towns, and counties, and in addition to relate the history of constitutional government from the landing of the Anglo-Saxons in England to the present time, all in the space of little more than two hundred pages. The necessary consequence is, that, in spite of condensation and brevity of expression, no part of the work is thoroughly done. The least satisfactory part, as might be expected, is that relating to local affairs; the town and county governments differing so widely in different States, that no single description will apply to them all. For instance: Mr. Thorpe says that the school directors of the town levy the school taxes, that the selectmen make the local laws and ordinances, that the county has the care and support of the poor, and that there is a county superintendent of schools; but, though these statements may be true of his own State of Pennsylvania, they are wholly untrue of Massachusetts. As for the history of constitutional government, which occupies the introductory part of this book, that obviously requires a separate work; and the chapters here given to it are altogether inadequate. We may add that the book contains a facsimile of the Declaration of Independence, several fancy pictures of historical events, and a gaudy spread eagle for frontispiece, none of which are likely to contribute much to political education.

A Text-Book of Elementary Biology. By R. J. HARVEY GIBSON. London and New York, Longmans, Green, & Co. 16^o. \$1.75.

MR. GIBSON'S experience as a teacher of biology has satisfied him, that, in order to instruct the student in this most important department, the beaten track must be left, and a new departure taken. To properly appreciate it, and to benefit by its study, a student must first undergo a preliminary training in the facts and

conclusions of physics and chemistry, and, in addition, must devote not a little time and labor to studying the application of the more general laws of these sciences to the special phenomena of plant and animal life. In this text-book the author has summarized briefly the principal conclusions of the inorganic sciences, devoting special attention to those laws on which the higher science of biology is founded, and has endeavored to keep prominently in the foreground the dependence of biology on physics and chemistry, and the relationship of morphological and physiological details to general principles.

Matter, energy, the classification of chemical compounds, and the laws of chemical change, are discussed in the first chapter; and the author then proceeds to consider protoplasm in its many and varied aspects. Individual and tribal life, with distribution and classification, are thoroughly treated.

The *Proteita*, *Protophyta*, *Protozoa*, *Metaphyta*, and *Metazoa* are described in most minute detail. The illustrations are excellent, and are to a great extent original. The typography and general execution of the book leave nothing to be desired. As a text-book of elementary biology, it is one of the best that have ever been published.

Chemical Lecture Notes. By PETER T. AUSTEN. New York, Wiley. 12°. \$1.

THIS book is not intended as a text-book, but is simply a collection of notes and observations on certain topics, which, experience as a teacher of chemistry in Rutgers College and the New Jersey State Scientific School has shown Professor Austen, give the student more or less trouble. While no attempt has been made to include all the rocks and shoals on which chemical students suffer shipwreck, still the author has succeeded in making lucid many of the topics which are not rendered sufficiently intelligible by the average text-book. Valence, atomicity, the laws of Boyle, Charles, and Mariotte, can no longer be a mystery to a student of these lecture-notes. We recommend them to those who have found difficulty in comprehending the intricacies of modern chemistry, and equally to those who would escape the hard places in this science, so numerous even when studied with the best of helps and teachers.

AMONG THE PUBLISHERS.

WE have received from A. Lovell & Co. "Greene's Language Half-Blanks, No. 1," by H. R. Greene, a pamphlet designed to teach the elements of English grammar by means of exercises and diagrams. Examples are given of the parts of speech, and the construction of the sentence is duly explained, and the pupil is then to write short sentences, the principal words being furnished him to illustrate what has been told him. These sentences are to be arranged in tables, and the different elements of the sentence indicated by certain marks written under the words. What the precise value of Mr. Greene's system may be, experience must decide; but marks and diagrams have no connection with language as such, and can at best be nothing more than very slight helps. The book is one of a series ending with a full grammar.

— Messrs. Ginn & Co. of Boston have issued "An Introduction to the Poetry of Robert Browning," by Professor William J. Alexander of Halifax, N.S. The author remarks on the difficulty experienced in understanding any new writer, and on the special difficulty of understanding Browning because of his obscurity; and he has prepared this work with the object of clearing up some of these difficulties, and making his author more comprehensible to the mass of readers. He finds the chief motive of Browning's work in his belief in the central doctrines of Christianity, which he has endeavored to illustrate and enforce. One chapter is given to Browning's philosophy, and another to his theory of art; and the remainder of the book is devoted to an account of his mental development as exhibited in his various works.

— D. Appleton & Co. will publish immediately a treatise by the Hon. Seymour Dexter of Elmira, N.Y., on "Co-operative Savings and Loan Associations," which will include an examination of building and loan associations, mutual savings and loan associations, accumulating fund associations, co-operative banks, etc.

The appendix will contain laws of New York, Pennsylvania, and Massachusetts, forms for Articles of associations, by-laws, account-books, and other useful information on the subject. The author, who is judge probate of Chemung County, has been president of the Chemung Valley Mutual Association for fourteen years, and is high authority on the subject of which he treats. They also announce "A Manual of Instruction in the Principles of Prompt Aid to the Injured," designed for military and civil use, by Dr. Alvah H. Doty; and a new book by Mr. O. B. Bunce, entitled "The Story of Happinoland and other Legends," which is to be issued in the Gainsborough Series. The latter consists of four slight sketches,—"The Story of Happinoland" (which, being translated, is "Happy-no-land"), "A Millionaire's Millions," "The City Beautiful," and "John's Attic;" all of which, the latter, however, only slightly, involve questions in social science.

— Harper & Brothers have ready this week a concise instructive work on "Constitutional Government in Spain," by J. L. M. Curry, LL.D., predecessor of Mr. Perry Belmont as minister of the United States in Spain. It is the result of some years of close study of the subject, and of actual observation of Spanish political and social life during the author's official residence in the country. Valuable appendices are added, summarizing the careers of aspirants to the Spanish throne,—Fernando, Leopold, Duke of Montpensier, and Amadeo; giving sketches of Christina, Isabel, Alfonso XII., the Infantas, the Queen Regent, and Alfonso XIII.; describing the present condition of Spain in its political, social, and industrial aspects; and, lastly, explaining briefly the acquisition of Florida by the United States. They have also just ready "Choice Cookery," by Catherine Owen, author of "Ten Dollars Enough," etc., the object of which is to help those who wish to know at a glance what is newest and best in modern cookery.

— David McKay, Philadelphia, will shortly publish a new edition of Joel Cook's "Holiday Tour in Europe," formerly published by Porter & Coates.

— The *American Magazine* suspended publication last December.

— *The Index*, published by E. R. Walker, Chicago, is a little four-page monthly paper that will attempt to take "a glance at the leading features of the forthcoming periodicals."

— *Once a Week* has been enlarged, and includes a greater variety of contents. The most noticeable thing in the current number is the first instalment of a Stockton story, called after its heroine, "Ardis Claverden."

— *The Advance Sheet*, published by C. A. Watson, New York, will attempt to give a monthly survey of periodical literature, indexing the contents of the leading periodicals for the next month, with such comments as will make the announcements as attractive as possible.

— The two new volumes of "Letters of Carlyle" which Professor C. E. Norton has edited are mostly addressed to the various members of Carlyle's family, and afford a tolerably continuous account of his life from his marriage to the period when his fame was about to be established by the publication of his "French Revolution." Messrs. Macmillan are to publish them speedily.

— The new edition of Queen & Co.'s "Chemical Apparatus Catalogue" is now published. It contains 368 pages, with about 1,200 illustrations, and will be mailed to any address on receipt of fifty cents, which sum will be deducted from the first purchase made from it amounting to ten dollars or more. This is a very elaborate work, containing the most useful apparatus, and the firm feels confident that it will be considered by chemists a standard for reference. While the quality of the apparatus is maintained, most of the prices have been reduced.

— In the *Contemporary Review* for March (New York, Leonard Scott Publication Company), interest centres in the paper on the "Panama Canal," by Edward Whymper, with its intelligent diagrams and maps; Archibald Forbes criticises some of Lord Wolseley's recent utterances; Dr. Dale continues his interesting papers on Australia; Canon Wilberforce treats of Ireland's demands; and Mr. Clerke describes the observatory at the Cape of Good Hope.

HARPER'S READERS.

	Pages.	Introduction Price.	List Price.
HARPER'S First Reader	144	20cts.	24cts.
HARPER'S Second Reader	208	30 "	36 "
HARPER'S Third Reader	316	40 "	48 "
HARPER'S Fourth Reader	420	50 "	60 "
HARPER'S Fifth Reader			

[In Preparation.]

Although published less than six months ago Harper's Readers have already been adopted and are now in satisfactory use in

MORE THAN FIVE HUNDRED CITIES AND TOWNS

including NEW YORK CITY, PHILADELPHIA, JERSEY CITY, N.J., FALL RIVER, MASS., ITHACA, N.Y., JACKSON, MICH., ELGIN, ILL., PATERSON, N.J., and many other places of importance. They have been adopted by the Board of Education of

THE STATE OF SOUTH CAROLINA

for use in the schools of that state, and have received the official sanction of officers and school boards in

HUNDREDS OF COUNTIES AND COUNTRY DISTRICTS.

in all parts of the Union. They have also been adopted for supplementary use in the schools of CHICAGO, ILL., MINNEAPOLIS, MINN., DULUTH, MINN., PEORIA, ILL., and many others of the best schools in all parts of the country. They have not only been introduced into the schools of the places above referred to, but they have everywhere been received with favor and have been accorded, by teachers and others, the most enthusiastic commendation.

School committees and others whose duty it is to select text-books for schools should see these Readers before adopting others. Copies for examination will be sent on receipt of the introduction price.

HARPER & BROTHERS, Publishers,
FRANKLIN SQUARE, - - - - NEW YORK.

"**ENCYCLOPÆDIA BRITANNICA.**" Popular Reprint, \$2.50 per volume, 24 volumes, making the set complete, now ready for delivery. One-half the price of the Scribner & Stoddart editions, and less than one-third the price of the original English editions which we have reproduced in fac-simile texts, maps, plates and illustrations, same number of pages and same number of volumes.

Call and examine sets and compare with the other editions, all of which are in our office. Circulars and sample pages mailed.

"THE LITERARY MARVEL OF THE AGE."

THE HENRY G. ALLEN COMPANY, PUBLISHERS,
739 and 741 Broadway, New York.

Unfinished Worlds:

A STORY IN ASTRONOMY. By S. H. PARKES, F.R.A.S., F.L.S. With 9 Illustrative Diagrams. Price \$1.50, cloth.

"We have read this with profound interest. Mr. Parkes writes with a dignity and love of truth befitting so exalted a theme, with that glow of enthusiasm which a genuine student of the wonders of the heavens may be expected to feel."—*Nonconformist*.

"Mr. Parkes gives a deeply interesting account of the long series of experiments by Rev. Dr. Ballinger, which have a direct bearing on the late Mr. Darwin's theory of evolution, especially as it relates to the supposed transmutation of every elementary form of life into new and more advanced species."—*N. Y. Daily Herald*.

"No clearer or more readable book could be recommended. Excellent illustrative diagrams."—*Glasgow Herald*.

JAMES POIT & CO., PUBLISHERS,
Astor Place, New York.

Schools.

NEW JERSEY, PLAINFIELD.

THE CHESTNUTS.—Parents with daughters to educate, or orphan girls with companion, may find a comfortable home, with school instruction by applying to Miss E. E. Kenyon.

CONNECTICUT, NEW HAVEN.

MRS. CADY'S SCHOOL FOR YOUNG LADIES. Prepares for Smith and Wellesley, and admits to Vassar by Certificate. Circulars. Early application necessary.

VERMONT, BURLINGTON.

VERMONT EPISCOPAL INSTITUTE. Boarding School for Boys. Prepares for College or Business. Military drill. Terms moderate. Fifty-seventh half-year opens September 3, 1888. Send for catalogue.

H. H. ROSS, A.M., Principal.

Publications received at Editor's Office, Feb. 25-March 2.

AMERICAN Institute of Electrical Engineers, Transactions of the. Vol. V. New York, The Institute. 435 p. 8°.

GANGUILLET, E. and KUTTER, W. R. A General Formula for the Uniform Flow of Water in Rivers and other Channels. Tr. by R. Hering and J. C. Trautwine, Jr. New York, Wiley; London, E. & F. N. Spon. 240 p. 8°. \$4.

LAMARTINE, A. de. Jeanne d'Arc. Ed. by Albert Barrère. Boston, Heath. 188 p. 16°.

LAURIE, S. S. Occasional Addresses on Educational Subjects. Cambridge, Eng., University Pr. 215 p. 12°. (New York, Macmillan, \$1.25.)

MERRINAM, M. A Treatise on Hydraulics. New York, Wiley. 381 p. 8°. \$3.50.

THOMSON, W. Popular Lectures and Addresses. (Nature Series.) Vol. I. Constitution of Matter. London and New York, Macmillan. 460 p. 12°. \$2.

— The favorable reception accorded in the past to the Easter-card packets put up by H. H. Carter & Co., Boston, has encouraged this enterprising house to prepare their 1889 packages with even greater care than heretofore. Being one of the largest dealers in this class of goods in the country, and selling paper directly from the mills, they are enabled to give exceptionally good values. People dealing with them are sure to find their goods satisfactory.

— Contortionists and "Snake-men" will be described in the April *Contortier* by Dr. Thomas Dwight of the Harvard Medical School, who has made a thorough investigation of their peculiar anatomy. Photographs of several expert contortionists in their most wonderful feats will be reproduced in the article. Henrik Ibsen, the Norwegian dramatist, a literary genius little known in this country, is the subject of a paper in the same number. Charles Francis Adams's paper on "The Prevention of Railway Strikes" was written nearly three years ago, but held back by the author for fear that, in existing conditions, it might result in more harm than good. A practical scheme for giving employees a part in the management of the road is suggested. Pictures showing stages in the building of the great ocean steamers, the "City of New York" and others, will illustrate Mr. Rideing's article on "Ocean Greyhounds."

— At a regular meeting of the Nineteenth Century Club, New York, on the 9th of November last, a resolution was passed appointing a committee to prepare and publish a memorial volume to the founder and first president of the club, and to solicit subscriptions to defray the expenses. This volume is now ready for publication. The book will contain the funeral orations, the addresses delivered at the memorial meetings, and essays and letters since received. It will consist of about two hundred pages, octavo, printed on heavy Holland paper, and richly bound in levant morocco. This edition, upon which no pains or expense will be spared to make it worthy of the club and of the occasion, will cost five dollars per copy. For those who desire it, an edition, handsomely bound in cloth, will be supplied at a cost of three dollars per copy. As frontispiece there will be a portrait of Courtlandt Palmer. As the committee have decided to print only such copies of the memorial volume as are ordered in advance, it is desirable that no time should be lost in notifying John H. Beach, 25 East 57th Street, of the number of copies and the kind of binding which may be desired.

— Mr. Andrew Lang is a frequent contributor of leading articles on social and literary topics to the *London Daily News*; and some of his admirers think that not a little of his most characteristic writing is to be found in these "leaders," as the English call them. One of these admirers, with the author's permission, has gathered some thirty of these essaylets in a volume which Longmans, Green, & Co. will publish shortly, under the apt title of "Lost Leaders." Among the subjects treated are "Thackeray's Drawings," the "Art of Dining," "Phiz," "Amateur Authors," and the "Lending of Books."

— James W. Queen & Co., 924 Chestnut Street, Philadelphia, announce a clearance sale of microscopes, objectives, accessories, and sundries, and have issued a new catalogue. The firm's stock-taking strongly calls attention to the fact that some microscopical accessories (and other goods) have not shown, of late, such activity of commercial movement as is desirable. They have therefore picked them out, described them in their special catalogue, and cut the prices, to make them move along. The articles described in this list are new and perfect unless otherwise noted.

— The following are from the table of contents of the April number of *The Chautauquan*: "Gossip about Greece," by J. P. Mahaffy, M.A., of Dublin University; "Agesilaus," by Thomas D. Seymour, M.A., of Yale University; "Greek Art," by Clarence Cook; "Color in the Animal World," by the Rev. J. G. Wood; "What Inventors have done for Farming," by James K. Reeve; "The Care of the Insane," by A. G. Warner, Ph.D.; "Sunday Labor," by the Rev. Jesse H. Jones; "The First Presidential Inauguration," by Charles Carleton Coffin; "English Pronunciation," by Robert McLean Cumnock, of Northwestern University; "Stu-

dent Life in Paris," by F. M. Warren; "British Columbia," by Sheldon Jackson, D.D., United States general agent of education in Alaska; "Women's Clubs in London," by Susan Hayes Ward; "A Virginia Plantation," by C. W. Coleman; "The Secret Service of the Treasury Department," by Mrs. Carl Barus.

LETTERS TO THE EDITOR.

*Correspondents are requested to be as brief as possible. The writer's name is in all cases required as proof of good faith. The editor will be glad to publish any queries consonant with the character of the journal. Twenty copies of the number containing his communication will be furnished free to any correspondent on request.

Origin of Fish in Isolated Waters.

A FEW months ago I called attention to the abundance of fish in certain isolated ponds in Florida, which become dry at times. (*Science*, xii, p. 280). Mr. Henry W. Howe of Boston suggested in reply that fish may be transported from one pond to another by birds. This is an interesting suggestion, as indicating a possible explanation, though I am not aware that there is any evidence to that effect at present. Alligators might also be mentioned as a possible transporting agency. But any such means would seem to be inadequate to produce the observed results. Since my former communication, I have had further opportunity to investigate this subject. The past season in Florida has been a very unusual one. The rainy season, which usually begins in the peninsular portion of the State, about the 1st of June, failed to make its appearance, and a severe drought resulted. Ponds, swamps, creeks, and wells became dry. Then in the fall, when the rainy season usually closes, "the windows of heaven were opened," and a very wet fall and winter followed. But the ponds, which were dry for many weeks during the hottest part of the year, now swarm with little fish; and during the heavy rains fish could be seen not only in ponds, but in ditches beside the railroad, in ditches beside the fields, and in shallow rain pools which would dry in a few days, and had no connection with other waters. In fact, minnows have been almost abundant enough to give color to the old notion of the *raining-down* of fish, frogs, tom-cats; lean meat, etc., reports of which are occasionally seen in the newspapers. There is certainly some certain and rapid means of populating the waters of isolated and temporary pools, which is well worth investigating.

CHS. B. PALMER,

Orange Heights, Fla., March 11.

The Soaring of Birds.

I HOPE I may be allowed space for a few short comments on Messrs. Gilbert and Kimball's letters in *Science*, xiii, pp. 169 and 170.

My conception of relative velocity does not differ from Mr. Gilbert's, as he supposes, and accordingly the statements of his paper were as clear to me as the restatements of his letter. So far as his presentation of the differential motion theory of soaring is concerned, my only criticism was that his assumption as to the dynamical effect of the wind on the bird during the turn seemed to demand more than mere assertion. One of my statements as to what this assumption implied, Mr. Gilbert questions as follows: "I do not admit that during the turn his [the bird's] velocity relative to the earth will change by an amount equal to twice the velocity, relative to the earth, of the medium in which the turn is made." His velocity relative to the earth will change by an amount equal to twice his velocity relative to the medium." Both positions are correct, however. We are merely using the term "velocity" in different senses.—Mr. Gilbert as connoting both rate and direction of motion, I as connoting rate of motion simply. I used the term in this sense, because it was the sense in which Mr. Gilbert had used it when he asserted that the velocity of the bird relative to the air would be the same after a turn as before.

Both Mr. Gilbert and Dr. Kimball hold that the velocity of wind or bird relative to the earth "has nothing to do with the question." That surely depends, however, upon what the question is. If we undertake, as I did, to account for the fact that some birds are able, without flapping of wings, to describe paths which, *relatively to the earth*, are spirals about lines inclined upwards, velocities relative to the earth must be taken into consideration. If, how-

ever, the question is the somewhat simpler one of determining the conditions under which a bird can gain elevation without expending energy, velocities relative to the earth may, of course, be ignored.

There is, as I now see, a great advantage in making the simpler investigation first: for, as Dr. Kimball has clearly shown, as soon as we recognize the fact that the bird's motion relative to the medium depends only on their relative velocity, it becomes clear that gain of elevation, and consequently the whole phenomenon of soaring, is impossible in a uniform horizontal wind.

It follows that there was an error in my theory of soaring. Mr. Gilbert thinks it due in part to my assuming it to be possible for a bird to glide in a wind moving faster than itself, with its head to leeward; but I see no reason why birds should not accomplish this fact, and am satisfied that I have often seen them do it. He also holds that my bird, "in passing from a negative velocity relative to the air, to a positive velocity relative to the air, must pass through the phase of no velocity relative to the air, in which he is practically helpless." But I was dealing with the bird's component velocity in the line of the wind's motion; and he might always have a velocity relative to the air, though its component in that line might be zero. The error which I made was in assuming, that, under the conditions of flight to which I subjected my bird, the turn to leeward was possible. From the way in which I made him fly, it is clear that the resultant force exerted on him, at every point of his supposed path, must be upward and to leeward. That being the case, the turn to leeward could not be accomplished, and consequently the path he was supposed to describe was an impossible path.

I feel that I must apologize to those of your readers who may have followed me in what may fitly be called "a wild-goose chase."

J. G. MACGREGOR.

Dalhousie College, Halifax, N.S., March 8.

"Shall We Teach Geology?"

IN Professor Winchell's remarks on my review of his recent work, there are only two points that call for reply. First, as to the study of history, which, according to him, trains no faculty but verbal memory. He now says that his "criticisms on history contemplate it as a study urged upon children in the early stages of education," and that in the colleges it is pursued in a better way. But, even if imperfectly taught, history trains far more important faculties than verbal memory. It exercises the intellect generally quite as much as geology does, and it also calls into play the moral judgment and the sympathies, which geology does not. To Professor Winchell the old red sandstone may be a more important topic of study than the Roman Empire, and the plesiosaurus a more interesting object of contemplation than Washington or Columbus; but to the mass of men this is not so. As to the time that Professor Winchell would have spent on geology, I may have misapprehended his meaning; and, if so, I am glad to be corrected. I haven't his book by me at present; but, if I remember rightly, he says that the study ought to be taken up in the primary schools, and continued through the various grades, which I understood to mean that the subject should be studied more or less every year. He now says that he only wants it taken up several times at intervals, and not pursued continuously, which is more moderate. I do not see, however, how even so much study of geology is possible; because, not to speak of languages and literature, there are many sciences of greater importance than geology, which ought, therefore, to be studied first. Such are arithmetic and geometry, geography, physics, human physiology, psychology, ethics, civil polity, and history; and I do not see how even all of these can be taught in the public schools. If these views are correct, geology can be nothing but an optional study in the high schools and colleges, while in the lower schools it can have no proper place.

THE REVIEWER.

Curves of Literary Style.

IN the interesting researches on this subject by Professor Mendenhall described in your journal in 1887, words were classified according to the number of letters in them, and curves made ac-

ordingly. As he pointed out, there are many ways in which the principle of his method may be applied; and I have lately thought some instructive results might be obtained from examining sentences with regard to length, as measured by the number of words.

Length of sentences is a matter in which pronounced styles differ greatly. Doubtless this is associated with psychological peculiarities which it might be instructive to inquire into. The mental machine (so to speak) which, for example, turns out the long parenthetical sentences of Gladstone, must be very different in design from that which yields the simple and direct utterances of John Bright.

I have made an examination of 300 sentences in each of the following works: Carlyle's "French Revolution," De Quincey's "Confessions," and Johnson's "Rambler." The number of words in each sentence was counted, and the sentences grouped accordingly. Then the sentences with words up to 10 were added together, those with words from 10 to 20, from 20 to 30, and so on. The accompanying curves were then obtained from these data. Let it be clearly understood what they mean. The plain line curve (for Carlyle) means that in the 300 sentences of the passage selected there were 62 containing words varying in number up to 10, while 100 had from 10 to 20, and so on. The result is roughly as we might expect: short sentences form the bulk of the Carlyle passage, his maximum being in the class 10 to 20, and sentences of more than 50 words are comparatively few. There are none beyond 100. De Quincey and Johnson, on the other

NUMBERS OF STYLE FROM CARLYLE, DE QUINCEY, AND JOHNSON.

Carlyle, heavy line; De Quincey, broken line; Johnson, light line with dots.

hand, have an abundance of longer sentences. De Quincey's most numerous class is that of 20 to 30 words; Johnson's, 30 to 40. But the curve of the former does not die down till after 110 to 120 words (really there was one inordinate sentence of 170, not shown in the diagram); while Johnson's is further protracted to 130 to 140.

I do not affirm the constancy of these curves: they only apply to the specified passages of 300 sentences. These few lines are merely by way of suggestion, and should any reader have the time and patience to pursue the inquiry further, he might, I think, find his labors not without some useful results.

It might be useful to see in what degree these curves approximate to constancy, or come short of it. One would like to know better than we do at present, how far the method, in any of its forms, is reliable or helpful in settling disputed questions of authorship, or in tracing anonymous literature to its source.

I would suggest an examination of the words used by speakers or writers as likely to be instructive.

A. B. M.

London, March 7.

Wind-Velocity and Wind-Pressure.

FROM time to time there have appeared discussions of these questions, so important to the practical engineer. It seems probable that the first of these, as far as relates to the relation between wind-movement and the travel of the cups of Robinson's anemometer, is soon to be definitely settled by indubitable experiments.

Professor Robinson first considered that the cups moved with one-third the wind-velocity, but this has been repeatedly called in question. In later times the more common method of investigation has been by whirling the anemometer on arms from 11 to 35 feet in length. It would seem as though arms of 11 feet could hardly give satisfactory results.

In discussions of this relation, the utmost confusion has arisen by wrongly considering the so-called "anemometer factor," and by making the same an entirely different quantity, and one from which it was supposed a "friction constant" had been separated. The statement that anemometers used in this country give 20 per cent too great wind-movement has been based on this misconception. Let x = "anemometer factor," w = wind-movement, and v = travel of the cups: we have,

$$x = \frac{w}{v} \quad (1)$$

Let a = "friction constant," and b = another constant: we have,

$$w = a + bv \quad (2)$$

Substituting the value of v in (1), we have,

$$x = \frac{bw}{w-a} \quad (3)$$

In experiments at St. Petersburg it was found that an anemometer with 6.72-inch arms and 4-inch cups, the same as used in this country, had $b = 2.47$, and $a =$ about 2 miles per hour. Assuming w at various velocities (5, 10, 15, 20, and 25), we obtain from (3), for x , 4.12, 3.09, 2.85, 2.74, and 2.68 respectively.

We see that even these earlier investigations show our anemometer (with factor 3) almost exactly correct for velocities from 10 to 15 miles per hour, while at less velocities it gives too little wind, and only about 12 per cent too much at 25 miles.

The wind records of this country had been so often called in question, the chief signal-officer finally made provision for an investigation of the question. The results in full will shortly be published. For our present purpose it will suffice to give the approximate results with our own anemometer, described above: with w at 5, 10, 15, 20, and 25, we obtain for x , 3.30, 3.11, 3.05, 2.98, and 2.89 respectively. These are very satisfactory, and show, that, except for high or low winds, the records are entirely correct.

It is rather singular that investigations have recently been made in England with a whirling arm of 29 feet, almost the same as that used in this country (28 feet). Unfortunately these experiments were made in the open air, and with a natural wind often 4 miles per hour. These currents vitiated all the results for velocities less than 30 miles per hour: in some cases the error amounted to 35 per cent. The helicoidal anemometer which was tested had a vane attached to keep it in the wind. It is of the same nature as the "air-meter," long since discarded for wind measurement, and only used for straight-line currents in mines or elsewhere. Fortunately in these experiments there was one day when it was nearly calm, and the results for that day do not differ from others made in a closed court. For velocities less than 25 miles per hour, these results are entirely unreliable and misleading, in the present state of our knowledge of the problem. An extended discussion of this question will be found in the *American Meteorological Journal* for March.

While much time has been expended on the above problem, yet much more has been spent in determining the relation between the velocity and pressure of the wind. This problem is by far the more difficult to solve, and to practical engineers the more important of the two. One thing is very gratifying, and that is that the investigations and practice so far have been almost entirely on the safe side; and the wonder is that buildings have not blown down at all, at least if engineers have ever allowed the commonly accepted figures to enter their computations. It is probable that in most cases engineers have assured themselves of a factor of safety far beyond any thing that any experiments have indicated. How is it that if, as some claim, the usual deductions have indicated three times too great pressure of the wind, any building has ever blown down? If we examine the matter, however, we shall find that most of the theoretical discussions, when separated from well-conducted investigations, will lead and have led far astray. One

of the most astonishing misapplications has been of Hagen's experiments, made with plates from 2 to 6 inches square at velocities from 1 to 4 miles per hour, to the side of a house 400 inches square, and with velocities of 60 or 70 miles per hour. But this is not all. Even Hagen's experiments are repudiated by those very persons who make this application, for the reason that they give an increasing pressure as the plate grows larger; so that with a house 400 inches square the pressure, according to Hagen's formula, would be seven times as great per square foot as on a plate 4 inches square. Certainly it would be very unscientific to discard the application of a formula where it does not seem satisfactory, and then apply the computation at another portion of the formula to that portion where we have discarded the same formula.

The best experiments with low velocities show no increase in pressure per square foot for plates from 4 to 24 inches square; and when plates have been exposed to the free wind, or at very high velocities, the result has shown

$$p = .005 sv^2,$$

in which p = pressure, s = surface in square feet, and v = velocity of wind in miles per hour. The recent English experiments were with a plate 6 inches square; and, even if they were not vitiated by untoward causes, it would be utterly impossible to reason from them to what the pressure would be on a surface four thousand times as great.

H. A. HAZEN.

Washington, March 18.

Queries.

44. EQUILIBRIUM. — In the account of his travels in the Colonies, the Marquis de Chastellux relates, that while at Albany, Jan. 1, 1782, he was surprised at the noise and racket with which the new year was ushered in; young folks, servants, and even negroes going from tavern to tavern, singing, and asking for drink. New Year's morning he took leave of Gen. Clinton, and adds, "I met nothing but drunken people in the streets, but what astonished me most was to see them not only walk, but run upon the ice, without falling or making a false step, whilst it was with the utmost difficulty I kept upon my legs" (*Travels in North America*, 1780-82, London, 1787, p. 441). Here is the best of evidence (for the marquis related only that which he saw; and his narrative, as well as being the most interesting "private" view of our country at that critical period, is also the most trustworthy), asserting that in some way a drunken person, or one not having to the fullest degree what we may call self-control, has a decided advantage over his supposed clearer-headed brother, who has refrained from the "flowing bowl." Is this actually the case, or is the advantage more apparent than real? Most of us have at some time noticed the truly wonderful balancings of a drunken person when in proximity to a curb or flight of stairs, and have commented thereon that a person conscious of the position could not imitate these contortions without danger to life and limb. Does extreme mental alertness, then, act as a detriment, while a blunted sensibility is an advantage to the person so conditioned? If so, the question becomes an important one, and not confined to conditions of self-imposed disability. We may need to know definitely at certain critical periods whether, in order to accomplish a given object, it is better that we should be partially blindfolded than that we should see and know all.

Answers.

42. LOOKING TO THE LEFT. — In answer to Query 42, permit me to suggest that seats on the right as one enters a play-house are preferred, because the action on the stage is to the observer's front and left. Troopers, choruses, and principals come on the stage from the left side; and dialogue, combat, and chief business generally occur in the corner back and to the left; while the mob, as in *Cæsar*, and *Spartacus the Gladiator*, fills in the right. This is the rule in our experience, modified in some cases by the limitations imposed by the building. Again, how will "42" account for the fact that abroad, confined perhaps to England only, if you turn to the left you are right, while if you turn to the right you are wrong?

L. E. J.

GUARANTY INVESTMENT COMPANY

CAPITAL \$250,000.

Hon. ALBERT H. HORTON (Chief Justice, Kansas Supreme Court), Topeka, Kan., Pres't.

7% Guaranteed Farm Mortgages 7%

The Company calls the special attention of Investors to the following points :

- I. All loans guaranteed and interest payable semi-annually at the Importers' & Traders' National Bank, New York.
- II. Unusual fulness of information, not only about the security itself, but about the general development of the section where the farm is located.
- III. An examination each year of the general business of the Company and the Mortgages themselves by a COMMITTEE OF INVESTORS sent for the purpose.
- IV. Many hundred Mortgages taken and NOT A SINGLE FORECLOSURE.
- V. Exhibitions in New York at frequent intervals, of Kansas and Nebraska Farm Products. The Exhibition at the American Institute in the fall of 1888, received the *HIGHEST AWARD* of superiority.
- VI. Monthly Bulletins giving full information about all Mortgages offered for sale.

Address for Monthly Bulletin and Investors' Committee Report for 1888,

THE CHEQUE BANK LIMITED.

ESTABLISHED IN LONDON, 1873.

CHIEF OFFICE, 4 Waterloo Place, Pall Mall, London.

TRUSTEES:

The Right Honorable JOHN BRIGHT, M.P.
The Right Honorable EARL BEAUCAMP.
Bankers: Bank of England.

The Capital of the Bank and its Guarantee Fund of 500,000 is invested in Government Securities.

The Bank does not discount Notes or Bills, nor speculate, but loans its Deposits against Government Securities, thus making the Cheque Bank Cheques EQUAL TO CASH—as the Bank of England Notes are.

The Cheque Bank issues Cheques singly or in books from ONE POUND upwards, for the use of Travelers, and for others remitting money to Europe, available in every town in England, Scotland, Ireland, and Wales. In every town of Europe, and all other parts of the world, Cheque Bank Cheques are accepted as Cash by all the British Government Offices.

VISITORS TO THE PARIS EXHIBITION this summer can get the Cheque Bank Cheques cashed at 50 Banking Houses in Paris.

Travelers and others holding Cheque Bank Cheques can have their mail matter addressed to them, care of the Cheque Bank, London, who will take charge of the same and forward to any address.

For Hand-Book containing List of upwards of 2000 of the principal Banking Houses throughout the World who Cash the Cheque Bank Cheques, and for all information, apply to the AGENCY.

EASTER CARDS BY MAIL.

All things young
and fair and sweet,
Come the Eastern-morn
to greet.

- We will send a complete set of the first six packages for \$3.50, and of the complete sets for \$5.00 and 50 cents for postage and registering, or to any one ordering \$5.00 worth of the above packets at one time, a \$1.00 packet will be sent free.
- No. 1.—For 50 Cents, and 4 Cents for Postage, 17 Prang & Co.'s and other fine Easter Cards, together with a handsome Birthday Booklet and a Lowell Calendar for 1889.
 - No. 2.—For 50 Cents, and 4 Cents for Postage, 10 large and finer Cards from the above publishers, with Card cut in form of an Easter Bell, and a Booklet Calendar by M. Ward & Co.
 - No. 3.—For \$1.00, and 6 Cents for Postage, a choice selection of 25 beautiful Cards of Prang's and Hildesheimer's, including a Souvenir Booklet (retail price, 35 cents) and a Satin Card and a Calendar.
 - No. 4.—For \$1.00, and 8 Cents for Postage, a selection of 10 of our largest and finest Cards, including an Easter novelty (retail price, 50 cents to \$1.00), or a Sonnet and Photograph from M. Hart or Beethoven or Haydn.
 - No. 5.—For 1.00 and 10 Cents for Postage 10 double Fringed Cards, each in a separate envelope, together with 2 handsome Cards of Children's Heads.
 - No. 6.—For 25 Cents, and 2 Cents for Postage, 10 Prang's, Tuck's, and other beautiful Cards, including a card cut in the form of a Cross.
 - No. 7.—For 50 Cents, and 4 Cents for Postage, 5 Easter Booklets and a Calendar for 1889.
 - No. 9.—BIRTHDAY PACKET. For 50 Cents, 17 Fine Cards of Prang's or Tuck's.
 - No. 10.—SUNDAY SCHOOL PACKET. For 50 Cents, 25 Cards, of Marcus Ward's, Prang's Cards, assorted.

STAMP OR POSTAL NOTES RECEIVED.
Pearl Cards, and other Novelties, at 15, 25, 50, 75 Cents and \$1.00 each for Birthday or Anniversary, which will be selected with care for different tastes and ages as specified.

TO TEACHERS ONLY
50 Marcus Ward's, Prang's, and other beautiful Cards, no two alike, for \$1.00 and 8 cents for Postage. Better assortment, \$2.00 and 10 cents for Postage. A very choice selection, no two alike, \$3.00 and 20 cents for Postage and Registering. And for 50 cents, and 4 cents for Postage, 25 Cards, no two alike, and a Calendar for 1889.

LOWEST PRICES IN THE UNITED STATES.
PAPER BY THE POUND. (no better or more elegant paper can be made). Common wealth Linen (a good medium priced linen paper), U. S. Treasury Bond (a tough paper, and very fashionable). Selling directly from mills to the consumer, we are able always to give lowest possible prices. Sample sheets of paper and envelopes, with prices and number of sheets to a pound, sent on receipt of 15 cents, and special prices to those taking orders for these papers with our card packets.

WHY YOU SHOULD USE Scott's Emulsion
OF Cod Liver Oil WITH HYPOPHOSPHITES.
It is used and endorsed by Physicians because it is the best.
It is Palatable as Milk.
It is three times as efficacious as plain Cod Liver Oil.
It is far superior to all other so-called Emulsions.
It is a perfect Emulsion, does not separate or change.
It is wonderful as a flesh producer.
It is the best remedy for Consumption, Scrofula, Bronchitis, Wasting Diseases, Chronic Coughs and Colds.
Sold by all Druggists.

THE SUBMERGING MONITOR CRUISER.

THE calls for models and designs of battle-ships and other war-vessels issued at various times by the Navy Department have resulted in the collection of many valuable plans and much data that will tend toward the construction of a navy of which the country may justly feel proud. Among the designs submitted that possess some novel features is that of Hon. J. R. Thomas, United States Representative from Illinois. It is intended in this vessel to com-

This cruiser is 235 feet in length, with a beam of 55 feet. She displaces 3,030 tons on a draught of 14½ feet. One great point to be observed by war-vessels intended for service on our coast is that of keeping the draught as small as possible, in order to insure the entry of these vessels into our ports on the south-eastern seaboard and the Gulf coast, many of which are so shallow that the heavy class of armored vessels at present afloat cannot enter. In this vessel the trouble has been overcome in a very great measure by keeping her draught inside of 15 feet. Her 7,500 horse-power

THE SUBMERGING MONITOR CRUISER.

bine large powers of offence and defence on as small an amount of displacement as is possible, recognizing that the efficiency of an armored vessel intended for ocean or coast purposes is to be measured by the disposition and character of her armament, the ability to use it in all reasonable weather, the protection afforded by the armor, the rate of speed both going ahead and turning, her cruising capacity without recoaling, and her habitability.

promises a speed of 17 knots, which may quite possibly be increased before the final plans are approved. The main battery consists of two 10-inch breech-loading rifles mounted in a turret, armored with 10 inches of steel plating. There is, in addition, a 15-inch Zalinski dynamite gun capable of throwing 800 pounds of high explosive at any distance within a range of two miles. There are two under-water bow torpedo-tubes, and a 6-inch rapid-fire gun on

the after deck. To these are added several rapid-fire guns of the smaller calibers, placed at the most commanding positions about the vessel. Her single military mast, in addition to the armored top, carries a powerful search-light mounted on an upper platform.

To give as great an armor protection as possible on a very limited displacement, the armor has been disposed in the form of an arc of a circle, turning downwards at the sides to four feet below the fighting-line. The armor on the crown is three inches in thickness, increasing to five inches at the sides. In order that the target presented to an enemy may be as small as possible, ballast-tanks have been provided capable of holding enough water to lessen the cruising freeboard three feet; so that the hull target exposed, in still water, will be represented by a segment of a circle, rising from zero at the water-line to four feet above at the centre of the vessel.

Particular attention has been paid to the subject of water-tight compartments, and the appliances for readily freeing them from water, both in case of accident and for restoring her to the normal line of floatation.

The ram bow with which this vessel is fitted, the speed that she is calculated to attain, and her handiness, all combine to render her a formidable and valuable addition to our seacoast defences, while her coal capacity, and ability to remain at sea at a 10-knot speed for over a month without recoaling, make her of the highest service as a cruiser.

Great care has been bestowed on the subject of light and ventilation below. A complete electric plant, comprising lights, fans, and blowers for ventilating, with all modern improvements, will undoubtedly do away with many of the ills that prevailed aboard former types of low-freeboard ironclads.

TOBIN BRONZE.

THIS alloy, manufactured by the Ansonia Brass and Copper Company, New York and Chicago, is attracting attention on account of its high elastic limit, tensile strength, toughness, and uniform texture. When rolled hot, the tensile strength of the bronze has been found to be greater than that of mild steel, certain tests showing for the bronze an average tensile strength of 79,600 pounds per square inch, and for steel 65,630 pounds; the elastic limits being 54,257 pounds and 36,510 pounds respectively.

Further, at a dead red heat, Tobin bronze can be forged and stamped as readily as steel. It is maintained by those who have experimented with and tested different kinds of metals with a view of determining their utility for forgings, that they find Tobin bronze to be the only bronze they have tried that will stand the process of drop-forging.

The alloy is lighter than copper, can be worked well in a lathe, and when finished has a bright golden color. Its freedom from blow-holes, durability, and anti-frictional properties adapt the bronze for use on all bearing surfaces; while its lightness, in addition to its great tensile strength, and resistance to the corrosive action of sea-water, renders it a suitable metal for condenser-plates, steam-launch shafting, ship sheathing, etc. When rolled in sheets and tempered or drawn in wire, it makes an excellent spring metal.

Its resistance to oxidation makes it a useful material wherever this is likely to occur. Some interesting experiments on this very point were made with the bronze by the inspectors of machinery of the United States steamers "Concord" and "Bennington."

With a view to determining its torsional endurance for steam-launch and yacht shafting, test specimens an inch long were cut at random from three-fourths-inch hot rolled rods, reduced to half an inch, and subjected to a torsional test in comparison with the best quality of machinery steel selected by Professor J. E. Denton, professor of experimental mechanics at Stevens' Institute, and tested by him on Thurston's autographic testing-machine. The results were as follows: average load at end of one-foot lever, which strained samples to elastic limit, for bronze 328 pounds, for steel 340 pounds; which ruptured samples, for bronze 633 pounds, for steel 711 pounds.

Another notable quality — its non-liability to give forth sparks — makes it invaluable for gunpowder machinery and gunpowder tools of every description.

A LARGE ELECTRIC-CURRENT CONDUCTOR.

A NEW departure in current conductors for electric-railway purposes has been taken by the Daft Company, who are now operating trains on a section of the Ninth Avenue Elevated Road in this city. The new kind of conductor is shown in the accompanying picture, which is a view on the road mentioned, looking south from Fourteenth Street. The conductor, which is supported by heavy insulated cast-iron brackets, runs along outside the outer guard-rail of each track. It is of round iron, three inches in diameter, and is surmounted by, and in perfect electrical contact with, a bar of phosphor bronze three-eighths of an inch thick by one inch wide. This bar takes all the wear from the contact apparatus, and will retain a polished surface under all circumstances. The supporting bracket is made in two parts, as may be seen in the illustration, and has a grip sufficient to prevent all possibility of displacement

NEW DAFT CONDUCTOR, NEW YORK ELEVATED ROAD.

of the conductor. The conductor is elevated a considerable distance from the ties, and the supporting brackets are well insulated, so that the chances of loss of electric energy through leakage are reduced to a minimum.

The difference in cost of iron and copper admits of the greatly increased size of conductor, giving the same conductivity at much less expense.

The Daft Company are now equipping the Ninth Avenue road with this conductor from Fourteenth Street south to Rector Street station, near the Battery; the success attending the running of their trains north from Fourteenth Street during the past winter encouraging them to extend operations and equip a greater length of track as rapidly as possible.

A METEOROLOGICAL EXHIBITION.

SEVERAL months since, the New England Meteorological Society, following the annual custom of the Royal Meteorological Society of London, decided to hold a loan exhibition in Boston in connection with its fourteenth regular meeting. The exhibition was opened in the physical laboratory of the Massachusetts Institute of Technology, Jan. 15, and was continued seven days. Among those who sent apparatus were Mr. Rotch from his Blue

Hill Observatory, the United States Signal Office, Harvard College Observatory, the Institute of Technology, the Boston Water Works, and the Draper Manufacturing Company of New York. Owing to the generous response to the circular requesting the loan of articles, particularly by the United States Signal Service, the exhibition was a success, and was so well attended by visitors that it was continued three days longer than was originally intended. Now that the feasibility of such an exhibition has been demonstrated, it is to be hoped that others will follow, as there can be no doubt of their effect in stimulating the study of meteorology.

THE HORNIG DIRECT-POWER STEERING SYSTEM.

THE steering system herewith illustrated is the invention of Julius L. Hornig of Jersey City, N. J. It may be operated by steam, hydraulic, or pneumatic pressure, the last being preferable. The motor is attached directly to the rudder-head, as shown in the

FIGS. 1. AND 2.

illustrations, though a special form of the motor is made which may be placed in any convenient part of the vessel, connecting with the rudder by chains, ropes, or rods.

The motor is shown at *M* in Figs. 1 and 2, the usual tiller, *L*,

not being removed, so that the vessel may be steered by hand if necessary. In fact, either hand or power steering may be done, or both at once, as neither system interferes with the other. *I* and *K* are guide-pulleys for the usual tiller-ropes. *R, R* are relief-cocks, and *P* is a regulator-cock for the brake.

FIGS. 3 AND 4.

The motor has three pistons, working in an annular chamber, as shown in Figs. 3 and 4. *A* and *C* are the bottom and top cases of the chamber; *B*, the pistons; *D*, the legs by which the motor is secured to the deck; *g*, the ports; *H*, the valve-chest; *I*, the inlet-pipe; and *K*, the outlet-pipe. *M* is a lever for working the regulator-valve *U*, and *N* is the main valve-lever. *S* is the rudder-head; *T*, the motor hub; and *F*, the end covers or abutments.

The reason for preferring pneumatic pressure to operate the motor is that liquids have practically no elasticity, and may freeze, while steam will condense. Air, on the other hand, is subject to no change; and its elasticity makes it an excellent cushion to receive the shocks of wave-blows, thus relieving the mechanism from sudden strain. In 1886 two boards of naval experts, acting under government instructions, made trials of pneumatic steering-gear, and reported its superiority over other methods.

The pressure-valve, which is operated by the lever, as shown in the cut, regulates the action of the pistons by supplying pressure to one side while relieving that on the other, or *vice versa*; while the pistons and rudder will remain stationary when the valve is kept closed. The motor may be controlled from any part of the vessel by any of the usual mechanical methods or by electrical transmission.

PROFESSORS AYRTON and PERRY announce that Messrs. J. W. Queen & Co. of Philadelphia, Penn., are alone authorized to sell their electrical measuring instruments in the United States and in Mexico, and all instruments sent to America which have satisfactorily passed their tests will bear the firm's name on them as American agents, as well as being accompanied by a certificate of accuracy.

PLATINUM.
